COMPOSITION FOR FORMING PASSIVATION LAYER, SEMICONDUCTOR SUBSTRATE HAVING PASSIVATION LAYER, PRODUCTION METHOD FOR SEMICONDUCTOR SUBSTRATE HAVING PASSIVATION LAYER, SOLAR CELL ELEMENT, PRODUCTION METHOD FOR SOLAR CELL ELEMENT, AND SOLAR CELL

A composition for forming a passivation layer, including a resin and a compound represented by Formula (I): M(OR1)m. In Formula (I), M includes at least one metal element selected from the group consisting of Nb, Ta, V, Y and Hf, each R1 independently represents an alkyl group having from 1 to 8 carbon atoms or an aryl group having from 6 to 14 carbon atoms, and m represents an integer from 1 to 5.
Description

[Technical Field]

[0001] The present invention relates to a composition for forming a passivation layer, a semiconductor substrate having a passivation layer, a method of producing a semiconductor substrate having a passivation layer, a photovoltaic cell element, a method of producing a photovoltaic cell element, and a photovoltaic cell.

[Background Art]

[0002] A conventional method of producing a silicon photovoltaic cell element is explained.

[0003] First, in order to improve efficiency by promoting an optical confinement effect, a p-type silicon substrate having a textured structure formed on its light receiving surface is prepared. Then, the p-type silicon substrate is subjected to treatment in a mixed gas atmosphere of phosphorus oxychloride (POCl₃), nitrogen and oxygen at a temperature of from 800°C to 900°C for several ten minutes, thereby uniformly forming an n-type diffusion layer. In this method, since phosphorus diffusion is performed using a mixed gas, an n-type diffusion layer is formed not only at a light-receiving surface but also at back and side surfaces. Therefore, side etching is performed in order to remove an n-type diffusion layer formed at side surfaces. In addition, an n-type diffusion layer formed at a back surface needs to be converted into a p⁺-type diffusion layer. Therefore, an aluminum paste is applied to the entire back surface, and this is subjected to a thermal treatment (sintering) in order to convert the n-type diffusion layer to a p⁺-type diffusion layer and to form an aluminum electrode, thereby obtaining an ohmic contact.

[0004] However, an aluminum electrode formed from an aluminum paste has a low electric conductivity. Therefore, an aluminum electrode, which is generally formed on an entire back surface, usually has a thickness of from about 10 µm to 20 µm after the thermal treatment (sintering) in order to reduce the sheet resistance. Furthermore, since there is a great difference between thermal expansion coefficients of silicon and aluminum, a large internal stress is generated in a silicon substrate on which an aluminum electrode is formed during thermal treatment (sintering) and cooling, thereby causing a damage to a crystalline interface, an increase in crystal defect, and warpage.

[0005] In order to solve the problems as described above, there is a method of reducing the thickness of the back surface electrode layer by reducing the amount of an aluminum paste to be applied. However, reducing the amount of aluminum to be applied results in insufficient amount of aluminum to diffuse from the surface to the inside of a p-type silicon semiconductor substrate. As a result, a desired BSF (Back Surface Field) effect (effect to enhance collection efficiency of generated carriers by the existence of a p⁺-type diffusion layer) cannot be achieved and the properties of a photovoltaic cell are deteriorated.

[0006] With reference to the above, a point contact method, in which an aluminum paste is applied onto a part of a silicon substrate surface to locally form a p⁺-type diffusion layer and an aluminum electrode (see, for example, Japanese Patent No. 3107287) is proposed.

[0007] In a case of a photovoltaic cell having a point contact structure at a surface opposite to the light-receiving surface (hereinafter, also referred to as a "back surface"), it is necessary to suppress a recombination velocity of minority carriers at a surface other than a region at which the aluminum electrode is formed. As a passivation layer for this purpose, a SiO₂ film is suggested (see, for example, Japanese Patent Application Laid-Open (JP-A No. 2004-6565). As a passivation effect achieved by forming a SiO₂ film, there is an effect of reducing the surface level density, which causes recombination, by terminating a dangling bond of a silicon atom in a back surface portion of a silicon substrate.

[0008] As another method to inhibit recombination of minority carriers, there is a method of reducing a minority carrier density by means of an electric field that generates a fixed charge in the passivation layer. Such a passivation effect is generally referred to as an electrical field effect, and an aluminum oxide (Al₂O₃) layer and the like are suggested as a material having a negative fixed charge (see, for example, Japanese Patent No. 4767110).

[0009] Such a passivation layer is generally formed by a method such as an ALD (Atomic Layer Deposition) method, a CVD (Chemical Vapor Deposition) method and the like (see, for example, Journal of Applied Physics, 104 (2008), 113703-1 to 113703-7). As a simple method of forming an aluminum oxide film on a semiconductor substrate, a method employing a sol gel process is suggested (see, for example, Thin Solid Films, 517 (2009), 6327-6330, and Chinese Physics Letters, 26 (2009), 088102-1 to 088102-4).

SUMMARY OF INVENTION

[Technical Problem]

[0010] Since a method described in Journal of Applied Physics, 104 (2008), 113703-1 to 113703-7 includes a complicated process such as vapor deposition, it is sometimes difficult to enhance productivity. A composition to be used
EP 2 876 670 A1

for a method of forming a passivation layer described in Thin Solid Films, 517 (2009), 6327-6330, and Chinese Physics Letters, 26 (2009), 088102-1 to 088102-4, may cause a trouble such as gelation over time and have an insufficient storage stability. Furthermore, a passivation layer that has excellent passivation effect using an oxide including a metal element other than aluminum, has not been studied sufficiently.

[0011] The present invention has been made in view of the above-described conventional problems, and aims to provide a composition for forming a passivation layer that exhibits excellent storage stability and enables formation of a passivation layer in a desired shape by a simple method. In addition, the present invention aims to provide a semiconductor substrate, a photovoltaic cell element and a photovoltaic cell that are obtained by using the composition for forming a passivation layer. Furthermore, the present invention aims to provide a method of producing the semiconductor substrate having a passivation layer and a method of producing the photovoltaic cell element.

[Solution to Problems]

[0012] Specific means for solving the above-mentioned problem are as follows.

<1> A composition for forming a passivation layer, including a resin and a compound represented by the following Formula (I):

\[ \text{M(OR}_1\text{)_m} \]  

in which, in Formula (I), M includes at least one metal element selected from the group consisting of Nb, Ta, V, Y and Hf, each R\text{\textsubscript{1}} independently represents an alkyl group having from 1 to 8 carbon atoms or an aryl group having from 6 to 14 carbon atoms, and m represents an integer from 1 to 5.

<2> The composition for forming a passivation layer according to <1>, further including a compound represented by the following Formula (II):

\[ \text{(R}_2\text{O)}_{3-n}\text{Al}(\text{R}_3\text{O})_n \]  

in which, in Formula (II), each R\text{\textsubscript{2}} independently represents an alkyl group having from 1 to 8 carbon atoms, n represents an integer from 0 to 3, each of X\text{\textsubscript{2}} and X\text{\textsubscript{3}} independently represents an oxygen atom or a methylene group, and each of R\text{\textsubscript{3}}, R\text{\textsubscript{4}} and R\text{\textsubscript{5}} independently represents a hydrogen atom or an alkyl group having from 1 to 8 carbon atoms.

<3> The composition for forming a passivation layer according to <1> or <2>, in which a content of the resin is from 0.1% by mass to 50% by mass.

<4> The composition for forming a passivation layer according to <2> or <3>, in which in Formula (II), each R\text{\textsubscript{2}} independently represents an alkyl group having from 1 to 4 carbon atoms.

<5> The composition for forming a passivation layer according to any one of <2> to <4>, in which in Formula (II), n represents an integer from 1 to 3, and each R\text{\textsubscript{5}} independently represents an alkyl group having from 1 to 4 carbon atoms.

<6> A semiconductor substrate having a passivation layer, including:

- a semiconductor substrate; and
- a passivation layer that is a thermally-treated product of the composition for forming a passivation layer according to any one of <1> to <5> and that is provided at an entire or partial surface of the semiconductor substrate.
A method of producing a semiconductor substrate having a passivation layer, the method including:

- a process of forming a composition layer by applying the composition for forming a passivation layer according to any one of <1> to <5> onto an entire or partial surface of a semiconductor substrate; and
- a process of forming a passivation layer by subjecting the composition layer to a thermal treatment.

A photovoltaic cell element, including:

- a semiconductor substrate having a pn junction of a p-type layer and an n-type layer that are connected;
- a passivation layer that is a thermally-treated product of the composition for forming a passivation layer according to any one of <1> to <5> and that is provided at an entire or partial surface of the semiconductor substrate; and
- an electrode provided at at least one layer selected from the group consisting of the p-type layer and the n-type layer.

A method of producing a photovoltaic cell element, the method including:

- a process of forming a composition layer by applying the composition for forming a passivation layer according to any one of <1> to <5> onto a surface of one side or both sides of a semiconductor substrate, the semiconductor substrate having;
- a pn junction of a p-type layer and an n-type layer that are connected and an electrode on one or more layers selected from the group consisting of the p-type layer and the n-type layer;
- a process of forming a passivation layer by subjecting the composition layer to a thermal treatment.

The photovoltaic cell, including:

- the photovoltaic cell element according to <8>;
- and
- a wiring material provided on the electrode of the photovoltaic cell element

[Advantageous Effects of Invention]

According to the present invention, it is possible to provide a composition for forming a passivation layer that exhibits excellent storage stability and to enable formation of a passivation layer in a desired shape by a simple method. In addition, it is possible to provide a semiconductor substrate, a photovoltaic cell element and a photovoltaic cell that are obtained by using the composition for forming a passivation layer. Furthermore, it is possible to provide a method of producing the semiconductor substrate having a passivation layer and a method of producing the photovoltaic cell element.

DESCRIPTION OF EMBODIMENTS

[0015] In the present specification, the term "process" as used herein includes not only an independent process but also a process that is not clearly distinguishable from one another, so long as it can attain its object. The numerical value range expressed as "A to B" indicates a range that includes A as a maximum value and B as a minimum value, respectively. Furthermore, in the present specification, unless otherwise indicated, when there are plural kinds of substances that correspond to a component, the content of the component refers to the total contents of the substances. The term "layer" includes a construction having a shape formed on a part of a region, in addition to a construction having a shape formed on an entire region.

<Composition for forming passivation layer>

[0016] The composition for forming a passivation layer includes a compound represented by the following Formula (I) (hereinafter, also referred to as a Formula (I) compound) and a resin. The composition for forming a passivation layer may include other components, if necessary.

\[
M(OR_1)^m \quad (I)
\]

[0017] In Formula (I), M includes at least one metal element selected from the group consisting of Nb, Ta, V, Y and Hf. R_1 represents an alkyl group having from 1 to 8 carbon atoms or an aryl group having from 6 to 14 carbon atoms. m represents an integer from 1 to 5.

[0018] A composition for forming a passivation layer including the above components is applied to a semiconductor substrate and is then subjected to a thermal treatment (sintering), thereby forming a passivation layer having excellent passivation effect in a desired shape. In addition, the composition for forming a passivation layer includes a Formula (I) compound, whereby the occurrence of problems such as gelation is suppressed, and storage stability over time is excellent.

[0019] Furthermore, a method using a composition for forming a passivation layer according to the present invention is a simple and highly productive method that does not require a deposition apparatus or the like. In addition, by using the method, a passivation layer can be formed in a desired shape without a complicated process such as a masking treatment. In addition, the composition for forming a passivation layer includes a Formula (I) compound, whereby the occurrence of problems such as gelation is suppressed and storage stability over time is excellent.

[0020] In the present specification, a passivation effect of a semiconductor substrate can be evaluated by measuring the effective lifetime of minority carriers in a semiconductor substrate on which a passivation layer is applied, by a microwave reflection photoconductivity decay method with a device such as WT-2000PVN manufactured by Semilab Japan K.K., and WCT-120 manufactured by Sinton Instruments Inc.

[0021] Effective lifetime \( \tau \) is represented by the following Formula (A) in which \( \tau_b \) represents a bulk lifetime inside a semiconductor substrate and \( \tau_S \) represents a surface lifetime at a surface of a semiconductor substrate. The smaller the surface level density at a surface of the semiconductor substrate is, the longer the \( \tau_S \) is, which results in longer effective lifetime \( \tau \). Alternatively, as the defects such as dangling bonds inside the semiconductor substrate decrease, bulk lifetime \( \tau_b \) becomes longer, which results in longer effective lifetime \( \tau \). That is, measurement of effective lifetime \( \tau \) enables evaluation of interfacial properties between the passivation layer and the semiconductor substrate, as well as internal properties of the semiconductor substrate such as dangling bonds.

\[
1/\tau = 1/\tau_b + 1/\tau_S \quad (A)
\]

[0022] The longer the effective lifetime \( \tau \) is, the slower the recombination velocity of the minority carriers is. By using
a semiconductor substrate having a longer effective lifetime for a photovoltaic cell element, the conversion efficiency thereof is improved.

[0023] The storage stability of a composition for forming a passivation layer can be evaluated by viscosity variation over time. Specifically, a shear viscosity $\eta^0$ at 25 °C at a shear rate 10 s$^{-1}$ of a composition for forming a passivation layer immediately after the formation thereof (within 12 hours), and a shear viscosity $\eta^{30}$ at 25 °C at a shear rate 10 s$^{-1}$ of a composition for forming a passivation layer 30 days after the formation are measured to make a comparison between $\eta^0$ and $\eta^{30}$, whereby, for example, the storage stability can be evaluated by a viscosity variation rate (%). A viscosity variation rate (%) over time can be obtained by dividing an absolute value of a difference of shear viscosities between immediately after and 30 days after the formation by the shear viscosity immediately after the formation and, specifically, can be calculated by the following formula. A viscosity variation rate of a composition for forming a passivation layer is preferably 30% or lower, more preferably 20% or lower, and still more preferably 10%.

$\text{Viscosity variation rate} = \frac{|\eta^{30} - \eta^0|}{\eta^0} \times 100$ (Equation)

(Compound represented by Formula (I))

[0024] The composition for forming a passivation layer includes at least one compound represented by Formula (I) (Formula (I) compound). Formula (I) compound is an alkoxide compound including at least one metal element selected from the group consisting of Nb, Ta, V, Y and Hf. By including Formula (I) compound in the composition for forming a passivation layer, a passivation layer having excellent passivation effect can be formed. The possible reason for this is as follows.

[0025] Because a metal oxide, which is formed by applying a thermal treatment (sintering) to a composition for forming a passivation layer that includes a Formula (I) compound, tends to become amorphous, it is thought that a fixed charge is readily generated due to defects in metal atoms or oxygen atoms. Further, it is thought that the fixed charge generates a charge near an interface of a semiconductor substrate, thereby reducing the concentration of minority carriers. As a result, it is thought that the recombination velocity of the carriers at the interface is suppressed, and excellent passivation effect is exhibited.

[0026] A binding mode in a passivation layer can be analyzed from a cross section of the semiconductor substrate by electron energy loss spectroscopy (EELS) with a scanning transmission electron microscope (STEM). In addition, a crystalline phase near an interface of a passivation layer can be determined by measuring an X-ray diffraction spectrum (XRD). Also, a fixed charge of a passivation layer can be evaluated by capacitance voltage measurement (CV).

[0027] In Formula (I), M includes at least one metal atom selected from the group consisting of Nb, Ta, V, Y and Hf. Among these, in view of storage stability of the composition for forming a passivation layer, operability during the preparation of the composition for forming a passivation layer, and a passivation effect of a passivation layer formed from a composition for forming a passivation layer, M is preferably at least one selected from the group consisting of Nb, Ta and Y, and more preferably Nb. In view of obtaining a negative fixed charge density of a passivation layer, M preferably includes at least one metal element selected from the group consisting of Nb, Ta, V, and Hf, and more preferably at least one selected from the group consisting of Nb, Ta, VO and Hf.

[0028] In Formula (I), each R$^1$ independently represents an alkyl group having from 1 to 8 carbon atoms or an aryl group having from 6 to 14 carbon atoms, preferably an alkyl group having from 1 to 8 carbon atoms, more preferably an alkyl group having from 1 to 4 carbon atoms. An alkyl group represented by R$^1$ may be straight or branched. Examples of an alkyl group represented by R$^1$ include a methyl group, an ethyl group, a propyl group, an isopropyl group, a butyl group, an isobutyl group, a sec-butyl group, a t-butyl group, a hexyl group, an octyl group and a 2-ethylhexyl group.

[0029] Examples of an aryl group represented by R$^1$ include a phenyl group.

[0030] An alkyl group and an aryl group represented by R$^1$ may have a functional group. Examples of a functional group of an alkyl group include a halogen atom, an amino group, a hydroxyl group, a carboxyl group, a sulfonic group and a nitro group. Examples of a functional group of an aryl group include a halogen atom, a methyl group, an ethyl group, an isopropyl group, an amino group, a hydroxyl group, a carboxyl group, a sulfonic group and a nitro group.

[0031] From the viewpoint of storage stability and a passivation effect, R$^1$ is preferably an unsubstituted alkyl group having from 1 to 8 carbon atoms, more preferably an unsubstituted alkyl group having from 1 to 4 carbon atoms.

[0032] In Formula (I), m represents an integer from 1 to 5. From the viewpoint of storage stability, m is preferably 5 when M is Nb, m is preferably 5 when M is Ta, m is preferably 3 when M is VO, m is preferably 3 when M is Y, and m is preferably 4 when M is Hf.

[0033] From the viewpoint of a passivation effect, the compound represented by Formula (I), preferably include at least one metal element selected from the group consisting of Nb, Ta and Y; and from the viewpoint of storage stability and a passivation effect, preferably at least one compound in which R$^1$ is an unsubstituted alkyl group having from 1 to
From the viewpoint of storage stability and obtaining a negative fixed charge density, the compound represented by Formula (I) preferably include a compound in which M is at least one selected from the group consisting of Nb, Ta, VO and Hf, and R¹ is an unsubstituted alkyl group having from 1 to 4 carbon atoms.

Examples of the compound represented by Formula (I) include niobium methoxide, niobium ethoxide, niobium isopropoxide, niobium n-propoxide, niobium n-butoxide, niobium t-butoxide, niobium isobutoxide, tantalum methoxide, tantalum ethoxide, tantalum isopropoxide, tantalum n-propoxide, tantalum n-butoxide, tantalum t-butoxide, tantalum isobutoxide, yttrium methoxide, yttrium ethoxide, yttrium isopropoxide, yttrium n-propoxide, yttrium t-butoxide, yttrium isobutoxide, vanadium methoxide, vanadium ethoxide, vanadium isopropoxide, vanadium n-propoxide, vanadium t-butoxide, vanadium isobutoxide, hafnium methoxide, hafnium ethoxide, hafnium isopropoxide, hafnium n-propoxide, hafnium t-butoxide and hafnium isobutoxide. Among these, niobium ethoxide, niobium n-propoxide, niobium n-butoxide, tantalum ethoxide, tantalum n-propoxide, tantalum t-butoxide, vanadium ethoxide oxide, vanadium n-propoxide oxide, vanadium t-butoxide oxide, vanadium isobutoxide oxide, hafnium methoxide, hafnium ethoxide, hafnium isopropoxide, hafnium n-propoxide, hafnium t-butoxide and hafnium isobutoxide are preferred. From the viewpoint of obtaining a negative fixed charge density, niobium ethoxide, niobium n-propoxide, niobium n-butoxide, tantalum ethoxide, tantalum n-propoxide, tantalum t-butoxide, vanadium ethoxide oxide, vanadium n-propoxide oxide, vanadium t-butoxide oxide, hafnium ethoxide, hafnium n-propoxide and hafnium n-butoxide are preferred.

As a compound represented by Formula (I), either a prepared product or a commercially available product may be used. Examples of a commercially available product include niobium pentamethoxide, niobium pentaoxide, niobium penta-1-propoxide, niobium penta-n-propoxide, niobium penta-sec-butoxide, tantalum pentamethoxide, tantalum penta-1-propoxide, tantalum penta-n-propoxide, tantalum penta-i-butoxide, tantalum penta-n-butoxide, tantalum penta-sec-butoxide, tantalum penta-t-butoxide, vanadium (V) trimethoxide oxide, vanadium (V) tri-1-propoxide oxide, vanadium (V) tri-n-propoxide oxide, vanadium (V) tri-t-butoxide oxide, vanadium (V) tri-1-butoxide oxide, vanadium (V) tri-n-butoxide oxide, vanadium (V) tri-sec-butoxide oxide, vanadium (V) tri-t-butoxide oxide, yttrium tri-1-propoxide, yttrium tri-n-butoxide, hafnium tetramethoxide, hafnium tetra-ethoxide, hafnium tetra-i-propoxide and hafnium tetra-t-butoxide, manufactured by Kojundo Chemical Lab. Co., Ltd.; niobium pentaethoxide, tantalum pentaethoxide, tantalum pentabutoxide, yttrium-n-butoxide, hafnium-tert-butoxide, manufactured by Hokko Chemical Industry Co., Ltd.; vanadium oxy triethoxide, vanadium oxy tri-normal-propoxide, vanadium oxy tri-normal-butoxide, vanadium oxy tri-iso-butoxide, and vanadium oxy tri-secondary-butoxide, manufactured by Nichia Corporation.

In order to prepare a compound represented by Formula (I), a known method such as a method in which a halide of a specific metal (M) and an alcohol are reacted in the presence of an inert organic solvent, and an ammonia or an amine compound is further added to withdraw a halogen (see JP-A No.63-227593 and JP-A No. H03-291247) can be used.

The compound represented by Formula (I) may be a compound having a chelate structure formed by mixing with a compound of a specific structure having two carbonyl groups. At least some of alkoxide groups in Formula (I) is preferably substituted with the compound of a specific structure to form an aluminum chelate structure. If necessary, a liquid medium may exist, and thermal treatment, addition of a catalyst, or the like may be performed. When at least a part of the alkoxide structure is substituted with a chelate structure, stability of the organic the Formula (I) compound against hydrolysis and polymerization reaction is improved, and storage stability of the composition for forming a passivation layer including it is further improved.

From the viewpoint of storage stability, the compound of a specific structure having two carbonyl groups is preferably at least one selected from the group consisting of a β-diketone compound and a β-keto ester compound and a malonic diester.

Examples of a β-diketone compound include acetylacetone, 3-methyl-2,4-pentanedione, 2,3-pentanedione, 3-ethyl-2,4-pentanedione, 3-butyl-2,4-pentanedione, 2,2,6,6-tetramethyl -3,5-heptanedione, 2,6-dimethyl -3,5-heptanedione and 6-methyl-2,4-heptanedione.

Examples of a β-keto ester compound include methyl acetoacetate, ethyl acetoacetate, propyl acetoacetate, isopropyl acetoacetate, isobutyl acetoacetate, butyl acetoacetate, t-butyl acetoacetate, pentyl acetoacetate, isopentyl acetoacetate, hexyl acetoacetate, n-octyl acetoacetate, heptyl acetoacetate, 3-pentyl acetoacetate, ethyl 2-acetylpentanoate, ethyl 2-methylacetoacetate, ethyl 2-butylacetoacetate, ethyl hexylacetoacetate, ethyl 4,4-dimethyl-3-oxovarelate, ethyl 4-methyl-3-oxovarelate, ethyl 2-ethy lacetoacetate, methyl 4-methyl-3-oxovarelate, ethyl3-oxohexanoate, ethyl 3-oxovarelate, methyl 3-oxohexanoate, ethyl 3-oxoheptanoate, methyl 3-oxoheptanoate, methyl 4,4-dimethyl-3-oxovarelate.

Examples of a malonic diester typically include dimethyl malonate, diethyl malonate, dipropyl malonate, diisopropyl malonate, dibutyl malonate, di-t-butyl malonate, dihexyl malonate, t-butylethyl malonate, diethyl methylmalonate, diethyl ethylmalonate, diethyl isopropylmalonate, diethyl butylmalonate, diethyl sec-butylmalonate, diethyl isobutylmalonate, diethyl 1-methylbutylmalonate.

When the Formula (I) compound has a chelate structure, the number of the chelate structure is not particularly
limited so long as it falls within the range of from 1 to 5. A number of a carbonyl group contributed to a chelate structure is not particularly limited. When M is Nb, a number of a carbonyl group contributed to a chelate structure is from 1 to 5; when M is Ta, a number of a carbonyl group contributed to a chelate structure is from 1 to 5; when M is VO, a number of a carbonyl group contributed to a chelate structure is from 1 to 3; when M is Y, a number of a carbonyl group contributed to a chelate structure is from 1 to 3; when M is Hf, a number of a carbonyl group contributed to a chelate structure is from 1 to 4.

[0044] The number of a chelate structure can be controlled by appropriately adjusting the mixing ratio of the Formula (I) compound and a compound that enables to form a chelate structure with a metal element. Alternatively, a compound having a desired structure may be selected from the commercially available metal chelate compounds.

[0045] The presence of a chelate structure in the Formula (I) compound can be confirmed by a conventional analysis method. For example, it is confirmed by analyzing infrared spectroscopy spectra, nuclear magnetic resonance spectra, a melting point, or the like.

[0046] The Formula (I) compound may be liquid or solid. From the viewpoint of a storage stability of a composition for forming a passivation layer and mixing property when a compound represented by the Formula (II) is used together, a compound represented by Formula (I) is preferably liquid at an ambient temperature (25°C). From the viewpoint of a passivation effect of a formed passivation layer and a storage stability of a composition for forming a passivation layer, Formula (I) compound showing solid is preferably a compound having excellent solubility or dispersibility against a solvent, and preferably a compound having stability in state of solution or dispersion.

[0047] The content of Formula (I) compound in the composition for forming a passivation layer may be appropriately selected, if necessary. From the viewpoint of storage stability and a passivation effect, the content of Formula (I) compound may be from 0.1 % by mass to 80% by mass, preferably from 0.5% by mass to 70% by mass, more preferably from 1% by mass to 60% by mass, and still more preferably from 1% by mass to 50% by mass, in the composition for forming a passivation layer.

(Compound represented by Formula (II))

[0048] The composition for forming a passivation layer of the present invention may further include at least one of a compound represented by the following Formula (II) (hereinafter, also referred to as an "specific organic aluminum compound").

\[
\begin{align*}
(R^2O)_{3-n}-\text{Al} & \\
\text{O} & \\
\text{R}^3 & \\
\text{X}^2 & \\
\text{R}^5 & \\
\text{R}^4 & \\
\text{X}^3 & \\
n &
\end{align*}
\]

[0049] In Formula (II), each R^2 independently represents an alkyl group having from 1 to 8 carbon atoms. n represents an integer from 0 to 3. Each of X^2 and X^3 independently represents an oxygen atom or a methylene group. Each of R^3, R^4 and R^5 independently represents a hydrogen atom or an alkyl group having from 1 to 8 carbon atoms.

[0050] The specific organic aluminum compound includes a compound that is referred to as aluminum alkoxide, aluminum chelate, or the like, and preferably includes an aluminum chelate structure in addition to an aluminum alkoxide structure. As described in Nippon Seramikkusu Kyokai Gakujitsu Ronbunshi, 97 (1989), 369 - 399, a organic aluminum compound is converted to an aluminum oxide (Al_2O_3) by thermal treatment (sintering). In that case, it is considered that the formed aluminum oxide tends to become amorphous, and a 4-fold coordinated aluminum oxide layer tends to be formed near the interface with a semiconductor substrate, and a large negative fixed charge attributed to a 4-fold coordinated aluminum oxide tends to be obtained. As a result, it is considered that a passivation layer having excellent passivation effect is formed.

[0051] In addition to the above, it is considered that a passivation effect is further improved in a passivation layer due
to the combination of the compounds represented by Formula (I) and Formula (II), respectively. Moreover, by performing thermal treatment (sintering) to a compound represented by Formula (I) and a compound represented by Formula (II) in a mixed state, it is considered that a complex metal alkoxide of a metal (M) represented by Formula (I) and aluminum (AI) is formed and physical properties such as reactivity and vapor pressure are improved. As a result, it is considered that the passivation layer as a thermally-treated (sintered) product becomes denser and its passivation effect is further improved.

[0052] In Formula (II), each R² independently represents an alkyl group having from 1 to 8 carbon atoms, preferably an alkyl group having from 1 to 4 carbon atoms. An alkyl group represented by R² may be straight or branched. Examples of an alkyl group represented by R² include a methyl group, an ethyl group, a propyl group, an isopropyl group, a butyl group, an isobutyl group, a sec-butyl group, a t-butyl group, a hexyl group, an octyl group and a 2-ethylhexyl group. From the viewpoint of storage stability and a passivation effect, an alkyl group represented by R² is preferably an unsubstituted alkyl group having from 1 to 8 carbon atoms, more preferably an unsubstituted alkyl group having from 1 to 4 carbon atoms.

[0053] In Formula (II), each n represents an integer from 0 to 3. From the viewpoint of storage stability, n is preferably an integer from 1 to 3, and more preferably from 1 or 3. Each of X² and X³ independently represents an oxygen atom or a methylene group. From the viewpoint of storage stability, at least one of X² and X³ is preferably an oxygen atom.

[0054] Each of R³, R⁴ and R⁵ in Formula (II) independently represents a hydrogen atom or an alkyl group having from 1 to 8 carbon atoms. An alkyl group represented by R³, R⁴ and R⁵ may be straight or branched. An alkyl group represented by R³, R⁴ and R⁵ may have a functional group, or may be unsubstituted, and is preferably unsubstituted. Examples of an alkyl group represented by R³, R⁴ and R⁵ include an alkyl group having from 1 to 8 carbon atoms, preferably an alkyl group having from 1 to 4 carbon atoms. Examples of an alkyl group represented by R³, R⁴ and R⁵ include a methyl group, an ethyl group, a propyl group, an isopropyl group, a butyl group, an isobutyl group, a sec-butyl group, a t-butyl group, a hexyl group, an octyl group and an ethylhexyl group.

[0055] From the viewpoint of storage stability and a passivation effect, it is preferred that each of R³ and R⁴ in Formula (II) independently represents a hydrogen atom or an unsubstituted alkyl group having from 1 to 8 carbon atoms, more preferably a hydrogen atom or an unsubstituted alkyl group having from 1 to 4 carbon atoms.

[0056] From the viewpoint of storage stability and a passivation effect, R⁵ in Formula (II) is preferably a hydrogen atom or an unsubstituted alkyl group having from 1 to 8 carbon atoms, more preferably a hydrogen atom or an unsubstituted alkyl group having from 1 to 4 carbon atoms.

[0057] From the viewpoint of storage stability, the compound represented by Formula (II) is preferably a compound in which n is from 1 to 3, and each R² independently represents a hydrogen atom or an alkyl group having from 1 to 4 carbon atoms.

[0058] From the viewpoint of storage stability and a passivation effect, the compound represented by Formula (II) is preferably at least one selected from the group consisting of: a compound in which n is 0 and each R² independently represents an alkyl group having from 1 to 4 carbon atoms; and a compound in which n is from 1 to 3, each R² independently represents an alkyl group having from 1 to 4 carbon atoms, at least one of X² and X³ is an oxygen atom, each of R³ and R⁴ independently represents a hydrogen atom or an alkyl group having from 1 to 4 carbon atoms, and each R⁵ is independently a hydrogen atom or an alkyl group having from 1 to 4 carbon atoms.

[0059] More preferably, the compound represented by Formula (II) is at least one selected from the group consisting of: a compound in which n is 0 and each R² is independently an unsubstituted alkyl group having from 1 to 4 carbon atoms; and a compound in which n is from 1 to 3, each R² independently represents an unsubstituted alkyl group having from 1 to 4 carbon atoms, at least one of X² and X³ is an oxygen atom, each of R³ and R⁴ independently represents a hydrogen atom or an alkyl group having from 1 to 4 carbon atoms, and each R⁵ is independently a hydrogen atom or an alkyl group having from 1 to 4 carbon atoms.

[0060] Examples of a specific organic aluminum, in which n is 0 in Formula (II), (i.e. a specific aluminum trialkoxide) include aluminum trimethoxide, aluminum triethoxide, aluminum triisopropoxide, aluminum tri-n-butoxide, aluminum mono-sec-butoxy-diisopropoxide, aluminum tri-t-butoxide and aluminum tri-n-butoxide.

[0061] Examples of a specific organic aluminum compound represented by Formula (II) in which n is from 1 to 3 include aluminum ethyl acetooacetate diisopropylate [i.e. (ethylacetooacetate) aluminum isopropylate] and tris(ethyl acetooacetate) aluminum.

[0062] The specific organic aluminum compound represented by Formula (II) in which n is from 1 to 3 may be a prepared product or a commercially available product. Examples of the commercially available product include ALCH, ALCH-50F, ALCH-75, ALCH-TR, ALCH-TR-20 (all trade names) manufactured by Kawaken Fine Chemicals Co., Ltd.

[0063] A specific organic aluminum compound represented by Formula (II) in which n is from 1 to 3 can be prepared by mixing an aluminum trialkoxide with a foregoing compound of a specific structure having two carbonyl groups.

[0064] When an aluminum trialkoxide is mixed with a compound of a specific structure having two carbonyl groups, at least some of alkoxide groups in the aluminum trialkoxide is substituted with the compound of a specific structure to form an aluminum chelate structure. If necessary, a liquid medium may exist, and thermal treatment, addition of a catalyst,
or the like may be performed. When at least a part of the aluminum alkoxide structure is substituted with an aluminum chelate structure, stability of the specific organic aluminum compound against hydrolysis and polymerization reaction is improved, and storage stability of the composition for forming a passivation layer including it is further improved.

The compound of a specific structure having two carbonyl groups includes a β-diketone compound, a β-keto ester compound as described above, and from the viewpoint of storage stability, a malonic diester, and preferably at least one selected from the group consisting of a β-diketone compound, a β-keto ester compound and a malonic diester.

When the specific organic aluminum compound has an aluminum chelate structure, the number of the aluminum chelate structure is not particularly limited so long as it falls within the range of from 1 to 3. In particular, from the viewpoint of storage stability, it is preferably 1 or 3, and from the viewpoint of solubility, it is more preferably 1. The number of an aluminum chelate structure can be controlled by appropriately adjusting the mixing ratio of an aluminum trialkoxide and a compound of a specific structure having two carbonyl groups. Alternatively, a compound having a desired structure may be selected from the commercially available aluminum chelate compounds.

From the viewpoint of a passivation effect and compatibility with a solvent that may be optionally added in the composition, the compound represented by Formula (II) is specifically preferably at least one selected from the group consisting of aluminum ethylacetacetate diisopropylate and aluminum triisopropoxide, and more preferably aluminum ethylacetacetate diisopropylate.

The presence of an aluminum chelate structure in a specific organic aluminum compound can be confirmed by the conventionally used analysis method. For example, it can be confirmed by analyzing infrared spectroscopy spectra, nuclear magnetic resonance spectra, a melting point, or the like.

The specific organic aluminum compound may be liquid or solid, and is not particularly limited. From the viewpoint of a passivation effect and storage stability, a specific organic aluminum compound that exhibits favorable stability at an ambient temperature (25°C) and favorable solubility or dispersibility in a solvent may be used to further improve homogeneity of the formed passivation layer, thereby tending to stably provide a desired passivation effect.

When the composition for forming a passivation layer includes a specific organic aluminum compound, the content thereof is not particularly limited. In particular, the content of the specific organic aluminum compound is preferably 0.5% by mass or more and 80% by mass or less, more preferably 1% by mass or more and 75% by mass or less, and particularly preferably 3% by mass or more and 70% by mass or less, provided that the total content of the Formula (I) compound and the specific organic aluminum compound is 100% by mass.

When the content of the specific organic aluminum compound is 0.5% by mass or more, storage stability of the composition for forming a passivation layer tends to be improved. When the content of the specific organic aluminum compound is 80% by mass or less, the passivation effect tends to be improved.

When the composition for forming a passivation layer includes a specific organic aluminum compound, the content of the specific organic aluminum compound in the composition for forming a passivation layer may be appropriately selected. From the viewpoint of storage stability and a passivation effect, the content of the specific organic aluminum compound in the composition for forming a passivation layer may be from 0.1% by mass to 60% by mass, preferably from 0.5% by mass to 55% by mass, more preferably from 1% by mass to 50% by mass, and still more preferably from 1% by mass to 45% by mass.

The composition for forming a passivation layer includes at least one kind of resin. By including a resin, morphological stability of a composition layer that is formed by applying the composition for forming a passivation layer on a semiconductor substrate is further improved, and a passivation layer can be formed in a desired shape at a region at which the composition layer has been formed.

The type of the resin is not particularly limited. A preferred resin is easy to adjust its viscosity to a range in which a favorable pattern can be formed upon application of the composition for forming a passivation layer on a semiconductor substrate. Examples of the resin include polyvinyl alcohol, polyacrylamide, a polyacrylamide derivative, polyvinyl amide, a polyvinyl amide derivative, polyvinyl pyrrolidone, polyethylene oxide, a polyethylene oxide derivative, polysulfonic acid, polycarboxylate alkysulfonic acid, cellulose, a cellulose derivative (cellulose ether such as carboxymethyl cellulose, hydroxyethyl cellulose and ethyl cellulose), gelatin, a gelatin derivative, starch, a starch derivative, sodium alginate, a sodium alginate derivative, xanthan, a xanthan derivative, guar gum, a guar gum derivative, scleroglucan, a sclerogluca derivative, tragacanth, a tragacanth derivative, dextran, a dextran derivative, a (meth)acrylic acid resin, a (meth)acrylate resin (such as an alkyl(meth)acrylate resin and a dimethylaminooethyl (meth)acrylate resin), a butadiene resin, a styrene resin, a siloxane resin, and a copolymer of these resins. These resins may be used singly or a combination of two or more kinds.

In the present specification, "(meth)acrylic acid" refers to at least one of "acrylic acid" and "methacrylic acid", and "(meth)acrylate" refers to at least one of "acrylate" and "methacrylate".
Among these resins, it is preferred to use a neutral resin that does not have either an acidic functional group or a basic functional group, from the viewpoint of storage stability and pattern formability. It is more preferred to use a cellulose derivative such as ethylcellulose, because a cellulose derivative is easy to adjust its viscosity and thixotropic property even with a small amount.

The molecular weight of the resin is not particularly limited, and is appropriately adjusted in view of a desired viscosity for the composition for forming a passivation layer. The weight average molecular weight of the resin is preferably from 1,000 to 10,000,000, and more preferably from 1,000 to 5,000,000, from the viewpoint of storage stability and pattern formability. The weight average molecular weight of a resin can be calculated from a calibration curve of a standard polystyrene, from a molecular weight distribution measured by GPC (gel permeation chromatography). The calibration curve is approximated by third degree equation using five sets of standard polystyrene samples (PStQuick MP-H, PStQuick B [TOSOH CORPORATION, trade name]). The measurement conditions of GPC are shown below.

**Apparatus:**

- **(Pump:** Model L-2130 [Hitachi High-Technologies Corporation])
- **(Detector:** Model L-2490 RI [Hitachi High-Technologies Corporation])
- **(Column oven:** L-2350 [Hitachi High-Technologies Corporation])
- **Column:** Gelpack GL-R440 + Gelpack GL-R450 + Gelpack GL-R400M (3 columns in total) (Hitachi Chemical Company, Ltd., trade name)
- **Column size:** 10.7 mm (inner diameter) x 300 mm
- **Eluent:** tetrahydrofuran
- **Sample Concentration:** 10 mg/2 mL
- **Injected Amount:** 200 μL
- **Flow Rate:** 2.05 mL/min.
- **Measurement Temperature:** 25°C

The content of the resin in the composition for forming a passivation layer may be appropriately selected, if necessary. For example, the content of the resin is preferably from 0.1% by mass to 50% by mass, and more preferably from 0.1% by mass to 30% by mass in the total mass of the composition for forming a passivation layer. In order to develop the thixotropic property so that pattern formation is readily performed, the content of the resin is still more preferably from 0.2% by mass to 25% by mass, particularly preferably from 0.5% by mass to 20% by mass, and extremely preferably from 0.5% by mass to 15% by mass.

The content ratio (mass ratio) of the Formula (I) compound (or a total mass of the Formula (I) compound and the Formula (II) compound when the composition further includes the Formula (II) compound) and the resin in the composition for forming a passivation layer may be appropriately selected, if necessary. Among these, from the viewpoint of pattern formability and storage stability, the content ratio (resin / Formula (I) compound) of the resin based on the Formula (I) compound or the content ratio (resin / Formula (I) compound + specific organic aluminum compound) of the resin based on a total mass of the Formula (I) compound and the specific organic aluminum compound when the composition further includes the specific organic aluminum compound is preferably from 0.001 to 1000, more preferably from 0.01 to 100, and still more preferably from 0.05 to 1.

(Liquid medium)

The composition for forming a passivation layer may further include a liquid medium (a solvent or a dispersion medium). By including a liquid medium in the composition for forming a passivation layer, adjustment of the viscosity becomes easier and applicability improves, thereby enabling formation of a more uniform passivation layer. The liquid medium is not particularly limited, and appropriately selected. In particular, the solvent is preferably a liquid medium that can dissolve a compound represented by Formula (I), a resin and a specific organic aluminum compound that is optionally added so as to form a uniform solution, and more preferably includes at least one kind of organic solvent.

The Formula (I) compound may sometimes hydrolyze and polymerize easily just as it is. However, the Formula (I) compound dissolved or dispersed in a liquid medium is suppressed from reacting, thereby tending to enhance storage stability.

Examples of a liquid medium typically include a ketone solvent such as acetone, methyl ethyl ketone, methyl-n-propyl ketone, methyl isopropyl ketone, methyl-n-butyl ketone, methyl isobutyl ketone, methyl-n-pentyl ketone, methyl-n-hexyl ketone, diethyl ketone, dipropyl ketone, disobutyl ketone, trimethyl nonanone, cyclohexanone, cyclopentanone, methyl cyclohexanone, 2,4-pentanediol and acetonitrile acetone; an ether solvent such as diethyl ether, methyl ethyl
The composition for forming a passivation layer may include an acidic compound or a basic compound. When preferably from 5% by mass to 98% by mass, and more preferably from 10% by mass to 95% by mass.

In particular, from the viewpoint of applicability with respect to a semiconductor substrate and pattern formability, a liquid medium preferably includes at least one selected from the group consisting of a terpene solvent, an ester solvent, and more preferably includes at least one selected from the group consisting of a terpene solvent, an ester solvent.

13
the composition for forming a passivation layer includes an acidic compound or a basic compound, from the viewpoint of storage stability, the content of the acidic compound or the basic compound in the composition for forming a passivation layer is preferably 1% by mass or less, and more preferably 0.1% by mass or less, respectively.

[0088] Examples of an acidic compound include a Bronsted acid and a Lewis acid. Specific examples include an inorganic acid such as hydrochloric acid and nitric acid, and an organic acid such as acetic acid. Examples of the basic compound include a Bronsted base and a Lewis base. Specific examples include an inorganic base such as an alkali metal hydroxide and an alkaline earth metal hydroxide, and an organic base such as trialkylamine and pyridine.

[0089] The composition for forming a passivation layer of the present invention may further include other components that are generally used in the art, if necessary, in addition to the above described components. Examples of the other components include, for example, a plasticizer, a dispersant, a surfactant, a thixotropic agent, a filler, other metal alkoxide compounds. In particular, the composition for forming a passivation layer preferably includes at least one selected from a thixotropic agent and a filler. By including at least one selected from a thixotropic agent and a filler, morphological stability of a composition layer that is formed by applying the composition for forming a passivation layer on a semiconductor substrate is further improved, and a passivation layer can be formed in a desired shape at a selective region at which the composition layer has been formed.

[0090] Examples of a thixotropic agent include a fatty acid amide, a polyalkylene glycol compound, an organic filler and an inorganic filler.

[0091] Examples of a polyalkylene glycol compound include a compound represented by the following Formula (III).

\[ R^6-(O-R^8)_{n-1}-O-R^7 \]  

[0092] In Formula (III), each of \( R^6 \) and \( R^7 \) independently represents a hydrogen atom or an alkyl group, and \( R^8 \) represents an alkylene group. \( n \) is an integer of 3 or more. Three or more of \( R^8 \) may be the same or different from each other.

[0093] Examples of a fatty acid amide include a compound represented by the following Formulae (1), (2), (3) and (4).

\[ R^9\text{CONH}_2 \]  

\[ R^9\text{CONH-}R^{10}\text{-NHCOR}^9 \]  

\[ R^9\text{NHCO-}R^{10}\text{-CONHR}^9 \]  

\[ R^9\text{CONH-}R^{10}\text{-N(R}^{11}\text{)}_2 \]  

[0094] In Formulae (1), (2), (3) and (4), each of \( R^9 \) and \( R^{11} \) independently represents an alkyl group having from 1 to 30 carbon atoms or an alkenyl group having from 2 to 30 carbon atoms, and \( R^{10} \) represents an alkylene group having from 1 to 10 carbon atoms. Two of \( R^{11} \) may be the same or different from each other.

[0095] Examples of an organic filler include particles or fibers composed of acrylic resin, cellulosic resin, polystyrene resin and the like.

[0096] Examples of an inorganic filler include particles of silicon dioxide, aluminum hydroxide, aluminum nitride, silicon nitride, aluminum oxide, zirconium oxide, silicon carbide and glass.

[0097] When an organic filler and an inorganic filler have a shape of particle, the average volume particle diameter thereof may be from 0.01 \( \mu \text{m} \) to 50 \( \mu \text{m} \). The average volume particle diameter of an organic filler and an inorganic filler can be measured with a laser diffraction scattering particle size distribution measuring apparatus (for example, Beckman Coulter, Inc., LS 13 320), and then refer to a value calculated as a median diameter by a particle size distribution. Alternatively, an average diameter can be obtained by observed with a SEM (scanning Electron Microscope).

[0098] Examples of the other metal alkoxide compounds include titanium alkoxide, zirconium alkoxide and silicon alkoxide.

(Physical property value)

[0099] The viscosity of the composition for forming a passivation layer is not particularly limited, and can be appropriately selected depending on the application method onto a semiconductor substrate, and the like. For example, the viscosity of the composition for forming a passivation layer can be from 0.01 Pa·s to 10,000 Pa·s. From the viewpoint of pattern formability, the viscosity of the composition for forming a passivation layer is preferably from 0.1 Pa·s to 1,000 Pa·s. The viscosity is measured at 25°C at a shear rate of 1.0 s\(^{-1}\), with a rotational shear viscometer.

[0100] The shear viscosity of the composition for forming a passivation layer is not particularly limited, and the composition for forming a passivation layer preferably has a thixotropic property. In particular, from the viewpoint of pattern formability, a thixotropic ratio \( \eta_1/\eta_2 \), which is obtained by dividing shear viscosity \( \eta_1 \) at a shear rate of 1.0 s\(^{-1}\) by shear...
viscosity $\eta$ at a shear rate of 10 s$^{-1}$, is preferably from 1.05 to 100, more preferably from 1.1 to 50. The shear viscosity is measured at a temperature of 25°C with a rotational shear viscometer equipped with a cone plate (diameter: 50 mm, cone angle: 1°).

[0101] Identification of the component in the composition for forming a passivation layer and determination of the content of the component can be performed by thermal analysis such as differential thermal - thermogravimetric simultaneous measurement (TG/DTA), spectral analysis such as nuclear magnetic resonance (NMR), infrared spectroscopy (IR), chromatographic analysis such as high-speed liquid chromatography (HPLC), gel permeation chromatography (GPC) or the like.

(Method of preparing composition for forming passivation layer)

[0102] Method of preparing composition for forming passivation layer is not particularly limited. For example, it can be formed by mixing a specific compound represented by Formula (I), a resin, and a specific organic aluminum compound, a liquid medium and the like that are optionally added by a conventionally used mixing method.

<Semiconductor substrate having passivation layer>

[0103] A semiconductor substrate having a passivation layer according to the present invention includes a semiconductor substrate and a passivation layer that is a thermally-treated (sintered) product of the composition for forming a passivation layer and is provided on an entire or partial surface of the semiconductor substrate. By having a passivation layer that is a thermally-treated product layer (sintered layer) of the composition for forming a passivation layer, the semiconductor substrate having a passivation layer exhibits excellent passivation effect.

[0104] The semiconductor substrate is not particularly limited, and appropriately selected from those conventionally used depending on the purpose. Examples of the semiconductor substrate include a substrate of silicon, germanium or the like to which a p-type impurity or an n-type impurity is doped (diffused). Among these, a silicon substrate is preferred. The semiconductor substrate may be either a p-type semiconductor substrate or an n-type semiconductor substrate. In particular, from the viewpoint of a passivation effect, a semiconductor substrate having a p-type layer at a side at which a passivation layer is formed is preferred. The p-type layer on a semiconductor substrate may be either a p-type semiconductor substrate or a p-type layer that is formed on an n-type semiconductor substrate or a p-type semiconductor substrate as a p-type diffusion layer or a p$^+$-type diffusion layer.

[0105] The thickness of the semiconductor substrate is not particularly limited, and appropriately selected depending on the purpose. For example, the thickness of the semiconductor substrate may be from 50 nm to 1,000 μm, and preferably from 75 μm to 750 μm.

[0106] The thickness of the passivation layer formed on a semiconductor substrate is not particularly limited, and appropriately selected depending on the purpose. For example, the thickness of the passivation layer is preferably from 5 nm to 50 μm, more preferably from 10 nm to 30 μm, and still more preferably from 15 nm to 20 μm.

[0107] The semiconductor substrate having a passivation layer can be applied to a photovoltaic cell element, a light-emitting diode element, or the like. For example, a photovoltaic cell element in which the semiconductor substrate having a passivation layer is used exhibits excellent conversion efficiency.

(Method of producing semiconductor substrate having passivation layer)

[0108] The method of producing a semiconductor substrate having a passivation layer according to the present invention includes: a process of applying the composition for forming a passivation layer on an entire or partial surface of a semiconductor substrate to form a composition layer; and a process of forming a passivation layer by subjecting the composition layer to a thermal treatment (sintering). The method may include other processes, if necessary.

[0109] By using a composition for forming a passivation layer according to the present invention, a passivation layer having excellent passivation effect can be formed in a desired shape by a simple method.

[0110] The method of producing a semiconductor substrate having a passivation layer preferably further includes a process of applying an alkaline aqueous solution onto the semiconductor substrate before a process of forming a composition layer. In other words, a surface of a semiconductor substrate is preferably washed with an alkaline aqueous solution before the application of a composition for forming a passivation layer on a semiconductor substrate. Washing with an alkaline aqueous solution can remove organic substances, particles or the like that exist on a surface of a semiconductor substrate, thereby further enhancing the passivation effect. An example of the method of washing with an alkaline aqueous solution includes RCA washing that is commonly known in the art. For example, a semiconductor substrate is immersed in a mixture of ammonium water and hydrogen peroxide water, treated at a temperature of from 60°C to 80°C to remove organic substances and particles, and washed. The washing time is preferably from 10 seconds to 10 minutes, and more preferably from 30 seconds to 5 minutes.
The method of applying a composition for forming a passivation layer on a semiconductor substrate to form a composition layer is not particularly limited. For example, a method of applying a composition for forming a passivation layer on a semiconductor substrate by a known application method may be employed. Examples of the method include immersion, screen printing, ink jetting, dispensing, spin coating, brushing, spraying, doctor blading and roll coating. Among these, screen printing and ink jetting are preferred from the viewpoint of pattern formability and productivity.

[0112] The amount of the composition for forming a passivation layer to be applied may be appropriately selected depending on the purpose. For example, it is appropriately adjusted so that the passivation layer to be formed has a desired thickness.

[0113] The composition layer formed with a composition for forming a passivation layer is subjected to a thermal treatment (sintering) to form a thermally-treated product layer (sintered product layer) derived from the composition layer, thereby forming a passivation layer on a semiconductor substrate.

[0114] The conditions for the thermal treatment (sintering) of the composition layer are not particularly limited, so long as a Formula (I) compound included in a composition layer and a specific organic aluminum compound that is optionally included are converted to a metal oxide or a complex oxide as a thermally-treated (sintered) product. In order to effectively impart a fixed charge to a passivation layer and to provide a more excellent passivation effect, the thermal treatment (sintering) is preferably performed at a temperature of from 300°C to 900°C, and more preferably from 450°C to 800°C. The temperature for the thermal treatment (sintering) mentioned herein refers to the highest temperature in the furnace used for the thermal treatment (sintering). The time for the thermal treatment (sintering) may be appropriately selected depending on the temperature for the thermal treatment (sintering). For example, the time for the thermal treatment (sintering) may be from 0.1 hours to 10 hours, and preferably from 0.12 hours to 5 hours. The time for the thermal treatment (sintering) mentioned herein refers to a retention time at the highest temperature.

[0115] The thermal treatment (sintering) may be performed with a diffusion furnace (for example, ACCURON CQ-1200, Hitachi Kokusai Electric Inc.) The atmosphere in which the thermal treatment (sintering) is performed is not particularly limited, and the thermal treatment may be performed in an air atmosphere.

[0116] The thickness of a passivation layer that is produced by a method of producing a semiconductor substrate having a passivation layer is not particularly limited, and appropriately selected depending on the purpose. For example, an average thickness of a passivation layer is preferably from 5 nm to 50 nm, more preferably from 10 nm to 30 nm, and more preferably from 15 nm to 20 nm.

[0117] The average thickness of the formed passivation layer is determined by measuring a thickness at three points with an interference type film thickness meter (e.g., F20 FILM THICKNESS MEASUREMENT SYSTEM, Filmetrics Corporation) by a routine method, and calculating an arithmetic average of the measured values.

[0118] The method of producing a semiconductor substrate having a passivation layer may further include a process of performing drying treatment of a composition layer formed from the composition for forming a passivation layer, between the process of applying a composition for forming a passivation layer onto a semiconductor substrate and the process of forming a passivation layer by performing thermal treatment (sintering). By including a process of performing drying treatment of the composition layer, a passivation layer having a more uniform thickness can be formed.

[0119] The process of performing drying treatment of a composition layer is not particularly limited, so long as at least a part of a liquid medium that may be included in the composition for forming a passivation layer can be removed. The drying treatment is, for example, a thermal treatment performed at a temperature of from 30°C to 250°C for one minute to 60 minutes, and preferably a thermal treatment performed at a temperature of from 40°C to 220°C for 3 minutes to 40 minutes. The drying treatment may be performed at an ambient pressure or under reduced pressure.

[0120] The method of producing a semiconductor substrate having a passivation layer may include a process of defatting a composition layer formed from the composition for forming a passivation layer between the process of applying a composition for forming a passivation layer and the process of forming a passivation layer by performing thermal treatment (sintering). By performing defatting of the composition layer, a passivation layer having a more uniform passivation effect can be formed.

[0121] The process of performing defatting of a composition layer is not particularly limited, so long as at least a part of a resin can be removed. The defatting process can be, for example, a thermal treatment performed at a temperature of from 250°C to 450°C for 10 minutes to 120 minutes, and preferably a thermal treatment performed at a temperature of from 300°C to 400°C for 3 minutes to 60 minutes. The defatting process is preferably performed in the presence of oxygen, and more preferably in an air atmosphere.

<Photovoltaic cell element>

[0122] A photovoltaic cell element of the present invention includes a semiconductor substrate having a pn junction of a p-type layer and an n-type layer that are connected, a passivation layer that is a thermally-treated (sintered) product of the composition for forming a passivation layer and is provided on an entire or partial surface of the semiconductor substrate, and an electrode provided on at least one of the p-type layer and the n-type layer. The photovoltaic cell
element may further include other constituents, if necessary.

[0123] By having a passivation layer formed from the composition for forming a passivation layer of the present 5 invention, the photovoltaic cell element exhibits excellent conversion efficiency.

[0124] The semiconductor substrate to which the composition for forming a passivation layer is to be applied is not 10 particularly limited, and appropriately selected from those conventionally employed depending on the purpose. As a 15 semiconductor substrate, a substrate as described above as the semiconductor substrate having a passivation layer 20 may be used, and the same applies to the preferably utilized ones. A surface on which a passivation layer is to be 25 provided preferably has a p-type layer.

[0125] The thickness of a passivation layer formed on a semiconductor substrate is not particularly limited, and 30 appropriately selected depending on the purpose. For example, an average thickness of a passivation layer is preferably 35 from 5 nm to 50 µm, more preferably from 10 nm to 30 µm, still more preferably from 15 nm to 20 µm. 40

[0126] The shape and the size of the photovoltaic cell element may not be limited. For example, the photovoltaic cell 45 element preferably has a rough square shape of from 125 mm to 156 mm for each side.

<Method of producing photovoltaic cell element>

[0127] A method of producing a photovoltaic cell element according to the present invention includes a process of 50 forming a composition layer by applying the composition for forming a passivation layer onto a surface of one side or both sides of a semiconductor substrate, the semiconductor substrate having; a pn junction composed of a p-type layer 55 and an n-type layer that are connected and an electrode on one or more layers selected from the group consisting of 60 the p-type layer and the n-type layer; a process of forming a passivation layer by subjecting the composition layer to a 65 thermal treatment.

[0128] By using the composition for forming a passivation layer of the present invention, a photovoltaic cell element 70 that exhibits excellent conversion efficiency can be produced by excellent printability and a simple method. In addition, 75 a passivation layer can be formed in a desired shape to enhance productivity of a photovoltaic cell element.

[0129] As a method of forming an electrode on at least one of a p-type layer and an n-type layer, a conventionally 80 used method may be employed. For example, an electrode can be formed by applying a paste for forming an electrode such as a silver paste, an aluminum paste or the like onto a desired region of a semiconductor substrate, and subjecting 85 the same to thermal treatment, if necessary.

[0130] The surface of a semiconductor substrate on which a passivation layer is to be provided may be either a p- 90 type layer or an n-type layer. In particular, a p-type layer is preferred from the viewpoint of conversion efficiency.

[0131] Details and preferred embodiments of the method of forming a passivation layer with the composition for forming 95 a passivation layer are similar to those as described above in connection with the method of producing a semiconductor substrate having a passivation layer.

[0132] The thickness of a passivation layer to be formed on a semiconductor substrate is not particularly limited, and 100 appropriately selected depending on the purpose. For example, an average thickness of a passivation layer is preferably 105 from 5 nm to 50 µm, more preferably from 10 nm to 30 µm, further preferably from 15 nm to 20 µm.

[0133] In the following, embodiments of the present invention will be illustrated with reference to the drawings.

[0134] Figure 1 is a process chart that schematically shows, as a cross sectional view, an example of the method of producing a photovoltaic cell element having a passivation layer according to the present embodiment. However, this process chart does not limit the present invention in any way.

[0135] In Figure 1 (1), p-type semiconductor substrate 1 is washed with an alkaline aqueous solution to remove organic 110 substances, particles or the like on a surface of p-type semiconductor substrate 1. By performing washing, a passivation effect is further improved. As a method of washing with an alkaline aqueous solution, a well-known RCA washing may be used.

[0136] Subsequently, as shown in Figure 1 (2), a surface of p-type semiconductor substrate 1 is subjected to alkaline 115 etching or the like, and a concave-convex surface (also referred to as texture) is formed. By forming a texture, reflection of sunlight at a light receiving surface can be suppressed. For alkaline etching, an etching solution containing NaOH and IPA (isopropyl alcohol) can be used.

[0137] Subsequently, as shown in Figure 1 (3), phosphorus or the like is thermally diffused at a surface of p-type 120 semiconductor substrate 1, and n*-type diffusion layer 2 having a depth of submicron order is formed and a pn junction is formed at an interface with a p-type bulk portion.

[0138] Examples of the method for diffusing phosphorus include, for example, a method including performing treatment in a mixed gas atmosphere including phosphorus oxychloride (POCl₃), nitrogen and oxygen at a temperature of from 125 800°C to 1000°C for several ten minutes. Since phosphorous is diffused utilizing a mixed gas, n*-type diffusion layer 2 is formed at a back surface and a side surface (not shown), in addition to the light receiving surface (front surface), as shown in Figure 1 (3). Further, PSG (silicate glass) layer 3 is formed on n*-type diffusion layer 2. Accordingly, side-etching is performed to remove PSG layer 3 and n*-type diffusion layer 2 formed at the side surface.
Subsequently, as shown in Figure 1 (4), PSG layer 3 formed at the light receiving surface and the back surface is removed with an etching solution such as hydrofluoric acid. Further, etching treatment is separately conducted to remove n⁺-type diffusion layer 2 formed at the back surface, as shown in Figure 1 (5).

Then, as shown in Figure 1 (6), anti-reflection film 4, such as silicon nitride, having a thickness of approximately 90 nm is formed on n⁺-type diffusion layer 2 at the light receiving surface by PECVD (plasma enhanced chemical vapor deposition) method or the like.

Then, as shown in Figure 1 (7), the composition for forming a passivation layer of the present invention is applied by screen printing or the like onto a part of the back surface. Then, after drying, thermal treatment (sintering) is performed at a temperature of from 300°C to 900°C to form passivation layer 5.

An example of a pattern of passivation layer at the back surface is shown as a schematic plan view in Figure 5. Figure 7 is an enlarged schematic plan view of part A in Figure 5. Figure 8 is an enlarged schematic plan view of the part B in Figure 5. In the case of a pattern of passivation layer 5 shown in Figure 5, as is seen from Figures 7 and 8, passivation layer at the back surface is formed in a pattern in which p-type semiconductor substrate 1 is exposed in the form of dots, excluding the area at which back surface power extraction electrode 7 is to be formed in the subsequent process. The openings in the form of dots are preferably regularly positioned with a dot diameter (Ld) and an interval (Lb). The dot diameter (Ld) and the interval (Lb) may be arbitrarily set. From the viewpoint of a passivation effect and suppressing recombination of minority carriers, Ld is preferably from 5 µm to 2 mm and Lb is preferably from 10 µm to 3 mm, and it is more preferable that Ld is from 10 µm to 1.5 mm and Lb is from 20 µm to 2.5 mm, and it is still more preferable that Ld is from 20 µm to 1.3 mm and Lb is from 30 µm to 2 mm.

In the above description, a passivation layer having a desired shape is formed by applying the composition for forming a passivation layer at a portion at which a passivation layer is to be formed (a portion other than the dotted openings), and by performing thermal treatment (sintering). Alternatively, a passivation layer may be formed by applying the composition for forming a passivation layer on an entire surface including dotted openings, and after performing thermal treatment (sintering), selectively removing a passivation layer formed at the dotted openings by laser irradiation, photolithography or the like. It is also possible to selectively apply the composition for forming a passivation layer by providing a mask with a masking material to a portion to which the composition for forming a passivation layer is not to be applied, such as dotted openings.

Subsequently, as shown in Figure 1 (8), a silver electrode paste that includes glass particles is applied onto a light receiving surface by screen printing or the like. Figure 4 is a schematic plan view showing an example of a light receiving surface of a photovoltaic cell element. As shown in Figure 4, a light receiving surface electrode is formed of light receiving surface current collector electrode 8 and light receiving surface power extraction electrode 9. To securely secure a light receiving area, the area for forming these light receiving surface electrodes needs to be small. Moreover, from the viewpoint of resistivity of a light receiving surface electrode and productivity, light receiving surface current collector electrode 8 preferably has a width of from 100 µm to 2 mm. Although two light receiving surface power extraction electrodes 9 are provided in Figure 4, from the viewpoint of power extraction efficiency (power generation efficiency) of minority carriers, the number of light receiving surface power extraction electrode 9 may be three or four.

On the other hand, as shown in Figure 1 (8), an aluminum electrode paste including a glass powder and a silver electrode paste including glass particles are applied onto a back surface by screen printing, or the like. Figure 9 is a schematic plan view showing an example of a back surface of a photovoltaic cell element. The width of back surface power extraction electrode 7 is not particularly limited, and from the viewpoint of connectivity or the like of a wiring material during a subsequent process of producing a photovoltaic cell, the width of back surface power extraction electrode 7 is preferably from 100 µm to 10 mm.

Light receiving surface current collector electrode 8 and light receiving surface power extraction electrode 9 are formed on the light receiving surface, and back surface current collector aluminum electrode 6 and back surface power extraction electrode 7 are formed on the back surface, by applying an electrode paste on the light receiving surface and the back surface, respectively, and after drying, performing thermal treatment (sintering) both on the light receiving surface and the back surface in an air atmosphere at a temperature of from approximately 450°C to 900°C.

After the thermal treatment (sintering), as shown in Figure 1 (9), at the light receiving surface, glass particles in the silver electrode paste for forming a light receiving electrode react with anti-reflection film 4 (i.e. fire-through), thereby achieving electrical connection (i.e. ohmic contact) between the light receiving surface electrodes (light receiving surface current collector electrode 8 and light receiving surface power extraction electrode 9) and n⁺-type diffusion layer 2. At the back surface, aluminum in an aluminum electrode paste diffuses into semiconductor substrate 1 at a region at which semiconductor substrate 1 is exposed in a dotted pattern (the area at which passivation layer 5 is not formed) upon thermal treatment (sintering), thereby forming p⁺-type diffusion layer 10. By using the composition for forming a passivation layer according to the present invention, a passivation layer having suppressed print bleeding can be formed in a desired shape, the passivation effect is enhanced, and a photovoltaic cell element that exhibits excellent power generation performance can be produced.
Figure 2 is a process chart expressed as a cross sectional view, which shows another example of a method of producing a photovoltaic cell element having a passivation layer according to the embodiment, in which a photovoltaic cell element can be manufactured in the same manner as in Figure 1, except that n+-type diffusion layer 2 of the back surface is removed by etching treatment, and the back surface is planarized. During the planarization, a method that includes immersing a back surface of a semiconductor substrate in a mixed solution of nitric acid, hydrofluoric acid and acetic acid, or a potassium hydroxide solution may be utilized.

Figure 3 is a process chart expressed as a cross sectional view that shows another example of the method of producing a photovoltaic cell element having a passivation layer according to the present invention. In this method, processes for forming a textured structure, n+-type diffusion layer 2 and anti-reflection film 4 on semiconductor substrate 1 (processes shown from Figure 3 (19) to (24)) are similar to the processes of the method shown in Figure 1.

After the formation of anti-reflection film 4, the composition for forming a passivation layer is applied, as shown in Figure 3 (25). In Figure 6, an example of a pattern of a passivation layer at the back surface is shown as a schematic plan view. In the pattern of a passivation layer shown in Figure 6, dotted openings are arranged on the entire back surface, and dotted openings are arranged also at a portion at which a back surface power extraction electrode is to be formed in the subsequent process.

Subsequently, boron or aluminum is allowed to diffuse at a portion of the back surface of semiconductor substrate 1 at which semiconductor substrate 1 is exposed in a dotted pattern (a portion at which passivation layer 5 is not formed), as shown in Figure 3 (26), and p+-type diffusion layer 10 is formed. When boron is allowed to diffuse during formation of a p+-type diffusion layer, the diffusion can be performed by a method of performing treatment in a gas containing boron trichloride (BCl₃) at a temperature of approximately 1,000°C. However, since diffusion is performed with a gas, as with the case of using phosphorus oxychloride, p+-type diffusion layer 10 may be formed on a light receiving surface, a back surface and a side surface of semiconductor substrate 1. Therefore, it is necessary to suppress unnecessary diffusion of boron in p-type semiconductor substrate 1, by forming a mask at a portion other than the dotted openings or the like.

When aluminum is allowed to diffuse in order to form p+-type diffusion layer 10, the diffusion can be performed by applying an aluminum paste to the dotted openings, performing thermal treatment (sintering) at a temperature of from 450°C to 900°C, allowing aluminum to diffuse through the dotted openings to form p+-type diffusion layer 10, and then performing etching with hydrochloric acid or the like to remove a thermally-treated product layer (sintered product layer) derived from the aluminum paste formed on p+-type diffusion layer 10.

Subsequently, aluminum is physically vapor-deposited on the entire back surface to form aluminum electrode 11, as shown in Figure 3 (27).

Thereafter, as shown in Figure 3 (28), a silver electrode paste including glass particles is applied onto the light receiving surface by screen printing or the like, and a silver electrode paste including glass particles is applied onto the back surface by screen printing or the like. The silver electrode paste is applied onto the light receiving surface in the shape of a pattern of the light receiving surface electrode as shown in Figure 4, and the silver electrode paste is applied on the back surface in the form of a pattern of the back surface electrode as shown in Figure 9.

After applying the electrode paste to the light receiving surface and the back surface, respectively, both of the light receiving surface and the back surface are subjected to a thermal treatment (sintering) in an air atmosphere at a temperature of from approximately 450°C to 900°C, thereby forming light receiving surface current collector electrode 8 and light receiving surface power extraction electrode 9 on the light receiving surface, and forming back surface collector electrode 11 and back surface power extraction electrode 7 on the back surface, respectively, as shown in Figure 3 (29). At the light receiving surface, a light receiving surface electrode and n+-type diffusion layer 2 are electrically connected to each other, and at the back surface, back surface collector electrode 11 formed by vapor deposition and back surface power extraction electrode 7 are electrically connected to each other.

In Figures 1 to 3, back surface current collector electrode 6 or 11, back surface power extraction electrode 7 are formed after passivation layer 5 is formed. Alternatively, passivation layer 5 may be formed after electrodes are formed in advance. Passivation layer 5 may be formed on a commercially available semiconductor substrate having an electrode.

The photovoltaic cell includes the photovoltaic cell element as described above and a wiring material provided on an electrode of the photovoltaic cell element. The electrode on which a wiring material is provided is a power extraction electrode or the like. As necessary, the photovoltaic cell includes plural photovoltaic cell elements that are connected via wiring material, and is sealed with a sealing material. The wiring material and the sealing material are not particularly limited, and may be appropriately selected from those conventionally used in the art.
EXAMPLES

[0158] The present invention is hereinafter specifically explained with reference to the examples, but the present invention is not limited thereto.

<Example 1>

(Preparation of composition for forming passivation layer 1)

[0159] Niobium pentaethoxide (1.2 g; Hokko Chemiel Industry Co., Ltd., structural formula: Nb (OC₂H₅)₅, molecular weight: 318.2), terpineol (18.5g; Nippon Terpene Chemicals, Inc., also referred to as TPO) and ethyl cellulose (0.3g; Nissin Kasei Co., Ltd., trade name: ETHOCEL 200 cps, also referred to as EC) were mixed to prepare composition for forming a passivation layer 1.

(Evaluation of thixotropy)

[0160] Immediately after the preparation (within 12 hours) of composition for forming a passivation layer 1, the shear viscosity of the composition was measured at a temperature of 25°C at a shear rate of 1.0 s⁻¹ and 10 s⁻¹, respectively, with a rotational viscometer (Anton Paar GmbH, MCR301) with a cone plate (diameter: 50 mm, cone angle: 1°).

[0161] The shear viscosity (η₁) at a shear rate of 1.0 s⁻¹ was 35.4 Pa·s, and the shear viscosity (η₂) at a shear rate of 10 s⁻¹ was 26.8 Pa·s. The thixotropic ratio (η₁/η₂) at a shear rate of 1.0 s⁻¹ and at a shear rate of 10 s⁻¹ was 1.32.

(Evaluation of storage stability)

[0162] The shear viscosity of composition for forming a passivation layer 1 as prepared above was measured immediately after the preparation (within 12 hours) and after being stored at 25°C for 30 days, respectively. The shear viscosity was measured with a rotational viscometer (Anton Paar GmbH, MCR301) equipped with a cone plate (diameter: 50 mm, cone angle: 1°) at a temperature of 25°C at a shear rate of 1.0 s⁻¹. The shear viscosity immediately after the preparation at 25°C was 35.4 Pa·s, and the shear viscosity after being stored at 25°C for 30 days was 36.9 Pa·s.

[0163] In the evaluation of storage stability, the result in which a change in shear viscosity after storage for 30 days is less than 10% is scored as A, the result in which a change in shear viscosity is 10% or more and less than 30% is scored as B, and the result in which a change in shear viscosity is 30% or more is scored as C. When the result is A or B, the storage stability of the composition for forming a passivation layer is considered to be favorable. The value of the shear viscosity measured immediately after the preparation and the evaluation results of the storage stability are shown in Table 2.

(Evaluation of printability)

[0164] In order to evaluate the printability of the composition for forming a passivation layer, two types of semiconductor substrates were used. Specifically, a monocrystalline p-type silicon substrate having a mirror-shaped surface (50 mm square, thickness: 625 μm or less, hereinafter referred to as Substrate A) and a monocrystalline p-type silicon substrate having a textured structure on its surface (50 mm square, thickness: 180 μm or less, hereinafter referred to as Substrate B) were used.

[0165] In order to evaluate the unevenness in printing, composition for forming a passivation layer 1 was applied by screen printing 10 times in succession onto Substrates A and B, respectively. As a result of visual observation, it was confirmed that nine of Substrate A and nine of Substrate B did not have unevenness in printing.

[0166] The result in which nine or more of the ten substrates did not have unevenness in printing is scored as A, the result in which six to eight of the ten substrates did not have unevenness in printing is scored as B, and the result in which five or less of the ten substrates did not have unevenness in printing is scored as C. When the result is A or B, the printability of the composition for forming a passivation layer is considered to be favorable.
subjected to a thermal treatment (sintering) at a temperature of 700°C for 10 minutes, and allowed to cool at room temperature (25°C).

For the evaluation of print bleeding, a dot diameter ($L_a$) of dotted openings in a passivation layer formed on a substrate after the thermal treatment (sintering) was measured. The dot diameter ($L_a$) was measured at ten points, and an average thereof was calculated. The dot diameter ($L_a$) was 332 μm for Substrate A, and 270 μm for Substrate B.

The result in which a decrease ratio of the dot diameter ($L_a$) after the thermal treatment (sintering) with respect to a dot diameter ($L_a$) immediately after printing (368 μm) is less than 10% is scored as A, the result in which the decrease ratio is from 10% to less than 30% is scored as B, and the result in which the decrease ratio is 30% or more is scored as C. When the result is A or B, suppression of the print bleeding of the composition for forming a passivation layer is considered to be favorable.

In the present specification, print bleeding refers to a phenomenon in which a composition for forming a passivation layer spreads on a substrate on which the passivation layer is formed.

In the present specification, print bleeding refers to a phenomenon in which a composition for forming a passivation layer spreads on a substrate on which the passivation layer is formed.

One of the ten Substrates A onto which composition for forming a passivation layer 1 was entirely applied, which were prepared for the evaluation of unevenness in printing as described above, was subjected to drying treatment by heating at 150°C for 3 minutes to evaporate a liquid medium. Subsequently, a substrate was subjected to a thermal treatment (sintering) at a temperature of 700°C for 10 minutes, and allowed to cool to room temperature (25°C), thereby preparing a substrate for evaluation. The thermal treatment (sintering) was performed using a diffusion furnace (AC-CURON CQ-1200, Hitachi Kokusai Electric Inc.) in an air atmosphere at the highest temperature of 700°C and a retention time of 10 minutes.

An effective lifetime (μs) of the substrate for evaluations obtained above was measured with a lifetime measurement device (Semilab Japan K.K., WT-2000PVN) at room temperature (25°C) by a microwave reflection photoconductivity decay method. The effective lifetime of a region of the obtained substrate for evaluation, at which the composition for forming a passivation layer was applied, was 198 μs.

The thickness of the passivation layer on the substrate for evaluation obtained above was measured with an interference-type film thickness meter (Filmetrics Corporation, F20 Thin Film Thickness Measurement System). The thickness of the passivation layer was 74 nm.

A capacitor having a MIS (Metal-Insulator-Semiconductor; metal/insulator/semiconductor) structure was prepared by forming plural aluminum electrodes having a diameter of 1 mm on the passivation layer of the substrate for evaluation by vapor deposition through a metal mask.

The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available prober and a commercially available LCR meter (Hewlett-Packard Company, 4275A). In a C-V curve obtained by plotting the voltage along the abscissa and the electrostatic capacitance along the ordinate, the voltage value at which the electrostatic capacitance begins to decrease as the voltage is increased ($V_{fb}$: flat band voltage) was determined, and the difference from the ideal flat band voltage in the case of not forming a passivation layer ($\Phi_{ms}$:-0.81 [V]) was calculated. Then, fixed charge density $N_f$ was calculated from the difference in flat band voltage ($V_{fb}$-$\Phi_{ms}$), the measured value of the electrostatic capacitance, the area of the aluminum electrode, and the elementary charge.

The fixed charge density $N_f$ is a negative value when the value of $V_{fb}$-$\Phi_{ms}$ is positive, i.e., $V_{fb}$ is greater than -0.81 [V]. As a result, the passivation layer exhibits negative fixed charge.

In the passivation layer prepared in Example 1, the fixed charge density $N_f$ was calculated from flat band voltage $V_{fb}$. As a result, it was found that the fixed charge was negative at -8.9 x 10^{10} cm².

A monocrystalline p-type semiconductor substrate (125 mm square, 200 μm in thickness) was prepared, and a textured structure was formed at a light receiving surface and at a back surface by performing alkaline etching. Then, in an atmosphere of a mixed gas of phosphorus oxychloride (POCl₃), nitrogen and oxygen, thermal treatment was performed at 900°C for 20 minutes, thereby forming an n⁺-type diffusion layer at the light receiving surface, the back surface and the side surfaces. Subsequently, side etching was performed to remove a PSG layer and an n⁺-type diffusion layer formed at the side surface, and a PSG layer formed at the light receiving surface and a PSG layer formed at the...
back surface were removed with an etching solution including hydrofluoric acid. Further, another etching treatment was performed to remove an n⁺-type diffusion layer at the back surface. Then, an anti-reflection film including silicon nitride of approximately 90 nm in thickness was formed on the n⁺-type diffusion layer at the light receiving surface by PECVD.

[0181] Subsequently, composition for forming a passivation layer 1 as prepared above was applied onto the back surface in the form of patterns shown in Figures 5, 7 and 8, dried at a temperature of 150°C for 5 minutes, and thermal treatment (sintering) was performed with a diffusion furnace (ACCURON CQ-1200, Hitachi Kokusai Electric Inc.) in an air atmosphere at the highest temperature of 700°C and a retention time of 10 minutes, thereby forming passivation layer 1. In Figures 5, 7 and 8, passivation layer 1 was formed at the back surface in the form of a pattern in which the p-type semiconductor substrate was exposed in a dotted manner, excluding the area in which a back surface power extraction electrode was to be formed in the subsequent process. The pattern of the dotted openings was the same as that used for the evaluation of print bleeding, and the dot diameter (Ld) was 368 μm and the interval (Lb) was 0.5 mm.

[0182] Subsequently, a commercially available silver electrode paste (PV-16A, Du Pont Kabushiki Kaisha) was applied onto the light receiving surface by screen printing in the form of a pattern shown in Figure 4. The electrode pattern composed of a light receiving surface current collector electrode of 120 μm in width and a light receiving surface power extraction electrode of 1.5 mm in width. The printing conditions (mesh of a screen block, printing speed, and printing pressure) were adjusted such that the thickness after performing thermal treatment (sintering) was 20 μm. Then, drying treatment was performed by heating at a temperature of 150°C for 5 minutes to evaporate a liquid medium.

[0183] On the back surface, a commercially available aluminum electrode paste (PVG-AD-02, PVG Solutions) and a commercially available silver electrode paste (PV-505, Du Pont Kabushiki Kaisha) were applied by screen printing in the form of a pattern shown in Figure 9. The pattern of the back surface power extraction electrode formed from a silver electrode paste was 123 mm × 4 mm.

[0184] Printing conditions (mesh of screen block, printing speed, and printing pressure) of a silver electrode paste and an aluminum electrode paste were adjusted such that the thickness of the back surface power extraction electrode and the back surface current collector electrode after thermal treatment (sintering) was 20 μm.

[0185] After performing printing with each of the electrode pastes, drying treatment was performed by heating at a temperature of 150°C for 5 minutes to evaporate a liquid medium.

[0186] Subsequently, thermal treatment (sintering) was performed with a tunnel furnace (single line delivery W/B tunnel furnace, Noritake Company, Limited) in an air atmosphere at the highest temperature of 800°C and a retention time of 10 seconds, thereby preparing photovoltaic cell element 1 on which intended electrodes were formed.

(Production of photovoltaic cell)

[0187] A wiring member (solder-plated flat wire for photovoltaic cell, product name: SSA-TPS 0.2 × 1.5 (20); plated with a Sn-Ag-Cu-based lead-free solder to a thickness up to 20 μm per either side of a copper wire of 0.2 mm in thickness and 1.5 mm in width, Hitachi Metals, Ltd (previous Hitachi Cable, Ltd.) was placed on the light receiving surface power extraction electrode and the back surface power extraction electrode of photovoltaic cell element 1 as obtained above, and the solder was melted with a tab wire stringing machine (NTS-150-M, Tabbing & Stringing Machine, NPC Incorporated) at the highest temperature of 250°C and a retention time for 10 seconds, thereby stringing the wiring member with the light receiving surface power extraction electrode and the back surface power extraction electrode.

[0188] Subsequently, a laminate having a structure of a glass plate 16 / sealant 14 / photovoltaic cell element 12 connected with wiring material 13 / sealant 14 / back sheet 15 in this order was prepared using a glass plate (tempered white glass plate, 3KWE33, Asahi Glass Co., Ltd.), a sealant (ethylene vinyl acetate; EVA) and a back sheet as shown in Figure 10. The laminate was subjected to vacuum lamination at a temperature of 140°C for 5 minutes with a vacuum laminator (LM-50×50, NPC Incorporated) so that a portion of the wiring member is exposed, thereby preparing photovoltaic cell 1.

[0189] The power generation performance of the photovoltaic cell was evaluated with a solar simulator (WXS-155S-10, Wacom Electric Co., Ltd.) and a measuring apparatus of a voltage-current (I-V) evaluation system (I-V CURVE TRACER MP-180, Eko Instruments). The measured values of Jsc (short-circuit current), Voc (open voltage), F.F. (form factor) and η (conversion efficiency), which indicate a power generation performance as a photovoltaic cell, were obtained according to JIS-C-8913 (2005) and JIS-C-8914 (2005). The obtained values were converted to a relative value with respect to the measured values of a photovoltaic cell as prepared in Comparative Example 1 (photovoltaic cell C1) that were defined as 100.0.

<Example 2>

[0190] Ethyl cellulose (Nissin Kasei Co., Ltd., trade name: ETHOCEL 200 cps) and aluminum ethylacetoacetate diisopropylate (ALCH) were added to the composition for forming a passivation layer prepared in Example 1. Specifically, the composition for forming a passivation layer 2 was prepared in the same manner as Example 1, except that the
content of niobium pentaethoxide (Hokko Chemial Industry Co., Ltd., structural formula: Nb(OC₂H₅)₅, molecular weight: 318.2) was 1.6 g, the content of ALCH was 1.0 g, the content of terpineol was 17.1 g and the content of ethyl cellulose was 0.3 g.

Subsequently, the thixotropic property, storage stability and printability (unevenness in printing and print bleeding) of composition for forming a passivation layer 2, and the effective lifetime of passivation layer 2 were evaluated in the same manner as Example 1, and the thickness and the fixed charge density were measured in the same manner as Example 1. Further, photovoltaic cell element 2 and photovoltaic cell 2 were prepared and the power generation performance was evaluated in the same manner as Example 1.

<Example 3>

The composition for forming a passivation layer prepared in Example 2 was used for the evaluation. Specifically, the printability (unevenness in printing and print bleeding) of composition for forming a passivation layer 3, and the effective lifetime of passivation layer 3 were evaluated in the same manner as Example 1, and the thickness and the fixed charge density were measured in the same manner as Example 1, and photovoltaic cell element 3 and photovoltaic cell 3 were prepared and the power generation performance was evaluated in the same manner as Example 1, except that the conditions for the thermal treatment (sintering) for composition for forming a passivation layer 2, which was performed in the preparation of the substrate for evaluating printability (unevenness in printing and print bleeding), the preparation of the substrate for evaluating the effective lifetime and the thickness of the passivation layer, and the preparation of the photovoltaic cell element, were changed from 700°C for 10 minutes to 600°C for 15 minutes.

<Example 4>

The composition for forming a passivation layer prepared in Example 2 was used for the evaluation. Specifically, the printability (unevenness in printing and print bleeding) of composition for forming a passivation layer 4, and the effective lifetime of passivation layer 4 were evaluated in the same manner as Example 1, and the thickness and the fixed charge density were measured in the same manner as Example 1, and photovoltaic cell element 4 and photovoltaic cell 4 were prepared and the power generation performance was evaluated in the same manner as Example 1, except that the conditions for the thermal treatment (sintering) for composition for forming a passivation layer 2, which was performed in the preparation of the substrate for evaluating printability (unevenness in printing and print bleeding), the preparation of the substrate for evaluating the effective lifetime and the thickness of the passivation layer, and the preparation of the photovoltaic cell element, were changed from 700°C for 10 minutes to 800°C for 8 minutes.

<Example 5>

Composition for forming passivation layer 3 was prepared in the same manner as Example 1, except that the contents were changed so that the content of vanadium (V) triethoxide oxide (Kojundo Chemical Lab. Co., Ltd., structural formula: VO(OC₂H₅)₃, molecular weight: 546.4) was 1.2 g, the content of aluminum ethylacetoacetate diisopropylate (Kawaken Fine Chemicals Co., Ltd., trade name: ALCH) was 0.8 g, the content of terpineol was 17.7 g and the content of ethyl cellulose (ETHOCEL 200cps) was 0.3 g.

Subsequently, the thixotropic property, storage stability and printability (unevenness in printing and print bleeding) of the composition for forming passivation layer 3, and the effective lifetime of passivation layer 5 were evaluated in the same manner as Example 1, and the thickness and the fixed charge density were measured in the same manner as Example 1. Further, photovoltaic cell element 5 and photovoltaic cell 5 were prepared and the power generation performance was evaluated in the same manner as Example 1.

<Example 6>

Composition for forming passivation layer 4 was prepared in the same manner as Example 1, except that the contents were changed so that the content of Hafnium tetra-t-butoxide (Kojundo Chemical Lab. Co., Ltd., structural formula: Hf(O-t-C₄H₉)₄, molecular weight: 470.9) was 1.2 g, the content of Aluminum trisethylacetoacetate (Kawaken Fine Chemicals Co., Ltd., trade name: ALCH-TR) was 1.2g, the content of terpineol was 17.3 g and the content of ethyl cellulose (ETHOCEL 200cps) was 0.3 g.

Subsequently, the thixotropic property, storage stability and printability (unevenness in printing and print bleeding) of the composition for forming passivation layer 4, and the effective lifetime of passivation layer 6 were evaluated in the same manner as Example 1, and the thickness and the fixed charge density were measured in the same manner as Example 1. Further, photovoltaic cell element 6 and photovoltaic cell 6 were prepared and the power generation performance was evaluated in the same manner as Example 1.
In the preparation of a composition for forming a passivation layer, niobium pentaethoxide (Hokko Chemical Industry Co., Ltd., structural formula: Nb(OC₂H₅)₅, molecular weight: 318.2), tantalum penta-n-butoxide (Kojundo Chemical Lab. Co., Ltd., structural formula: Ta(O-n-C₄H₉)₅, molecular weight: 546.4), terpineol and ethyl cellulose (ETHOCEL 200 cps) were used. Specifically, composition for forming a passivation layer 5 was prepared in the same manner as Example 1, except that the content of niobium pentaethoxide was 1.4 g, the content of tantalum penta-n-butoxide was 1.0 g, the content of terpineol was 17.3 g, and the content of ethyl cellulose was 0.3 g.

Subsequently, the thixotropic property, storage stability and printability (unevenness in printing and print bleeding) of composition for forming a passivation layer 5, and the effective lifetime of passivation layer 7 were evaluated in the same manner as Example 1, and the thickness and the fixed charge density were measured in the same manner as Example 1. Further, photovoltaic cell element 7 and photovoltaic cell 7 were prepared and the power generation performance was evaluated in the same manner as Example 1.

In the preparation of a composition for forming a passivation layer, niobium penta-n-butoxide (Kojundo Chemical Lab. Co., Ltd., structural formula: Nb(O-n-C₄H₉)₅, molecular weight: 458.5), vanadium (V) triethoxide (Kojundo Chemical Lab. Co., Ltd., structural formula: VO(OC₂H₅)₃, molecular weight: 546.4), aluminum ethylacetate diisopropylate (Kawaken Fine Chemicals Co., Ltd., trade name: ALCH), terpineol and ethyl cellulose (ETHOCEL 200 cps) were used. Specifically, composition for forming a passivation layer 6 was prepared in the same manner as Example 1, except that the content of niobium penta-n-butoxide was 1.6 g, the content of vanadium (V) triethoxide was 0.6 g, the content of ALCH was 0.6 g, the content of terpineol was 17.0 g, and the content of ethyl cellulose was 0.2 g.

Subsequently, the thixotropic property, storage stability and printability (unevenness in printing and print bleeding) of composition for forming a passivation layer 6, and the effective lifetime of a passivation layer 8 were evaluated in the same manner as Example 1, and the thickness and the fixed charge density were measured in the same manner as Example 1. Further, photovoltaic cell element 8 and photovoltaic cell 8 were prepared and the power generation performance was evaluated in the same manner as Example 1.

Composition for forming a passivation layer C2 that includes bismuth triethoxide (Kojundo Chemical Lab. Co., Ltd., structural formula: Bi(OC₂H₅)₃, molecular weight 344.2), terpineol and ethyl cellulose (ETHOCEL 200 cps), as shown in Table 1, was prepared without using a compound of Formula (I) (M includes a metal element selected from Nb, Ta, V, Y or Hf) used in the preparation of the composition for forming a passivation layer in Example 1.

Subsequently, the thixotropic property, storage stability and printability (unevenness in printing and print bleeding) of the composition for forming a passivation layer C2, and the effective lifetime of passivation layer C2 were evaluated in the same manner as Example 1, and the thickness and the fixed charge density were measured in the same manner as Example 1. Further, photovoltaic cell element C2 and photovoltaic cell C2 were prepared and the power generation performance was evaluated in the same manner as Example 1.
<Comparative Example 3>

[0207] Composition for forming a passivation layer C3 that includes titanium tetra-i-propoxide (Kojundo Chemical Lab. Co., Ltd., structural formula: Ti(O-i-C₃H₇)₄, molecular weight 284.2), terpineol and ethyl cellulose (ETHOCEL 200 cps), as shown in Table 1, was prepared without using a compound of Formula (I) (M includes a metal element selected from Nb, Ta, V, Y or Hf) used in the preparation of the composition for forming a passivation layer in Example 1.

[0208] Subsequently, the thixotropic property, storage stability and printability (unevenness in printing and print bleeding) of composition for forming a passivation layer C3, and the effective lifetime of passivation layer C3 were evaluated in the same manner as Example 1, and the thickness and the fixed charge density were measured in the same manner as Example 1. Further, photovoltaic cell element C3 and photovoltaic cell C3 were prepared and the power generation performance was evaluated in the same manner as Example 1.

<Comparative Example 4>

[0209] Photovoltaic cell element C4 and photovoltaic cell C4 were prepared and the power generation performance was evaluated, while not forming a passivation layer at the back surface in the preparation of a photovoltaic cell element. Specifically, a textured structure was formed at a light receiving surface and at a back surface, and an n⁺-type diffusion layer and an anti-reflection film of silicon nitride were formed to a thickness of approximately 90 nm at the light receiving surface by PECVD. Then, on the light receiving surface, a commercially available silver electrode paste (PV-16A, Du Pont Kabushiki Kaisha) was applied by screen printing in the form of a pattern shown in Figure 4, and subjected to drying treatment by heating at a temperature of 150°C for 5 minutes to evaporate a liquid medium. On the back surface, a commercially available aluminum electrode paste (PVG-AD-02, PVG Solutions) and a commercially available silver electrode paste (PV-505, Du Pont Kabushiki Kaisha) were applied by screen printing in the form of a pattern shown in Figure 9. After the application of the electrode pastes, drying treatment was performed by heating at a temperature of 150°C for 5 minutes to evaporate a liquid medium. The size and the printing conditions for the electrode pastes were the same as Example 1.

[0211] Subsequently, thermal treatment (sintering) was performed with a tunnel furnace (single line delivery W/B tunnel furnace, Noritake Company, Limited) in an air atmosphere at the highest temperature of 800°C and a retention time of 10 seconds, thereby preparing photovoltaic cell element C4 in which intended electrodes were formed.

[0212] Photovoltaic cell C4 was prepared by using photovoltaic cell element C4 in the same manner as Example 1, i.e., by connecting a wiring member to the light receiving surface power extraction electrode and the back surface power extraction electrode, assembling a laminate with a glass plate, a sealant and a back sheet, and performing vacuum lamination with a laminator.

Table 2
The results of the evaluation of shear viscosity, thixotropic property and storage stability of the compositions for forming a passivation layer, the evaluation of printability, the measurement of lifetime and thickness, and the evaluation of power generation performance of the photovoltaic cells, as performed in Examples 1 to 8 and Comparative Examples 1 to 4, are shown in Table 2.

In addition, the effective lifetime and power generation performance of a photovoltaic cell evaluated in Examples 1 to 8 were almost the same as those measured in Comparative Example 1, showing that a passivation layer having a passivation effect that was comparable to that of aluminum oxide (Al₂O₃) formed by an ALD method was formed by using the composition for forming a passivation layer of the present invention. The result of the measurement of the fixed charge density showed that the passivation layers prepared in Examples 1 to 8 exhibited a negative fixed charge, although the values were different thereamong.

Some of Examples 1 to 8 had the evaluation whose print bleeding is B. However, it is thought that an effect to the power generation performance of the print bleeding is reduced by employing, for example, a method of applying a composition for forming a passivation layer onto an entire area of the back surface and, after performing thermal treatment (sintering), removing the passivation layer in the form of a desired pattern, instead of a screen printing method as used in the Examples. Accordingly, as is seen in the Examples, it is thought that the occurrence of print bleeding per se would not cause a reduction in the power generation of a photovoltaic cell.

The power generation performance of a photovoltaic cell tends to become relatively higher in the case in which the composition for forming a passivation layer includes a compound of Formula (I) and a specific organic aluminum compound. It is thought that, by including a compound of Formula (I) and a specific organic aluminum compound in the composition for forming a passivation layer, for example, a composite oxide of a metal derived from a compound of Formula (I) and aluminum is formed by performing thermal treatment (sintering), and a passivation layer that is denser and greater in negative fixed charge is formed, thereby further improving a passivation effect.

The results of Examples 7 and 8 showed that in a case in which two kinds of Formula (I) compounds also exhibited a high passivation effect and contributed to an increase in the power generation performance of a photovoltaic cell.

The power generation performance of a photovoltaic cell prepared in Comparative Examples 2 and 3 was lower than Comparative Example 1 and Examples 1 to 8. As is seen from the measurement result of the fixed charge density, it is thought that a greater value of a fixed charge was generated from an oxide, i.e., bismuth oxide (Bi₂O₃) and titanium oxide (TiO₂) that was formed by performing thermal treatment (sintering) to the composition for forming a passivation layer C2 of Comparative Example 2, in which triethoxy bismuth was used, or the composition for forming a passivation layer C3 of Comparative Example 3, in which titanium tetra-i-propoxide was used, and therefore a sufficient passivation effect was not obtained.

The power generation performance of a photovoltaic cell prepared in Comparative Example 4 was lower than that in Comparative Example 1 and Examples 1 to 8. The reason for this is thought to be that aluminum was diffused at an entire area of the back surface of the semiconductor substrate during performing thermal treatment (sintering) after applying an aluminum electrode paste to the back surface because a passivation layer was not formed in a photovoltaic cell 4 prepared in Comparative Example 4, thereby increasing back surface recombination of minority carriers generated in a photovoltaic cell, as a result of not forming a passivation layer.

A passivation film, an application material, a photovoltaic cell element, and a silicon substrate having a passivation film of Reference Embodiment 1 are hereinafter described.

A passivation film that comprises aluminum oxide and niobium oxide and is used for a photovoltaic cell element having a silicon substrate.

The passivation film according to <1>, wherein a mass ratio of the niobium oxide to the aluminum oxide (niobium oxide / aluminum oxide) is from 30/70 to 90/10.

The passivation film according to <1> or <2>, wherein a total content of the niobium oxide and the aluminum oxide is 90% by mass or more.

The passivation film according to any one of from <1> to <3>, further including an organic component.

The passivation film according to any one of from <1> to <4>, which is a thermally-treated product of an application material including an aluminum oxide precursor and a niobium oxide precursor.

An application material that comprises an aluminum oxide precursor and a niobium oxide precursor, and is
used for formation of a passivation film of a photovoltaic cell element having a silicon substrate.

<7> A photovoltaic cell element that comprises:

- a p-type silicon substrate that comprises monocrystalline silicon or polycrystalline silicon, and has a light receiving surface and a back surface that is opposite to the light receiving surface;
- an n-type impurity diffusion layer that is formed on the light receiving surface of the silicon substrate;
- a first electrode that is formed on a surface of the n-type impurity diffusion layer of the light receiving surface of the silicon substrate;
- a passivation film that is formed on the back surface of the silicon substrate, the passivation film having plural openings and including aluminum oxide and niobium oxide; and
- a second electrode that is electrically connected to the back surface of the silicon substrate through the plural openings.

<8> A photovoltaic cell element that comprises:

- a p-type silicon substrate that comprises monocrystalline silicon or polycrystalline silicon, and has a light receiving surface and a back surface that is opposite to the light receiving surface;
- an n-type impurity diffusion layer that is formed on a light receiving surface of the silicon substrate;
- a first electrode that is formed on a surface of the n-type impurity diffusion layer of the light receiving surface of the silicon substrate;
- a p-type impurity diffusion layer that is formed on an entire or partial back surface of the silicon substrate, and doped with an impurity at a higher concentration than the silicon substrate;
- a passivation film that is formed on the back surface of the silicon substrate, the passivation film having plural openings and including aluminum oxide and niobium oxide; and
- a second electrode that is electrically connected to the p-type impurity diffusion layer of the back surface of the silicon substrate through the plural openings.

<9> A photovoltaic cell element that comprises:

- an n-type silicon substrate that includes monocrystalline silicon or polycrystalline silicon and has a light receiving surface and a back surface that is opposite to the light receiving surface;
- a p-type impurity diffusion layer that is formed on the light receiving surface of the silicon substrate;
- a second electrode that is formed on the back surface of the silicon substrate;
- a passivation film that is formed on the light receiving surface of the silicon substrate, the passivation film having plural openings and including aluminum oxide and niobium oxide; and
- a first electrode that is formed on the p-type impurity diffusion layer of the light receiving surface of the silicon substrate, and forms electrical connection with a surface at the light receiving side of the silicon substrate.

<10> The photovoltaic cell element described any one of from <7> to <9>, wherein a mass ratio of niobium oxide to aluminum oxide (niobium oxide / aluminum oxide) in the passivation film is from 30/70 to 90/10.

<11> The photovoltaic cell element according to any one of from <7> to <10>, wherein a total content of the niobium oxide and the aluminum oxide in the passivation film is 90% by mass or more.

<12> A silicon substrate having a passivation film that comprises:

- a silicon substrate; and
- the passivation film according to any one of from <1> to <5> that is provided on an entire or partial surface of the silicon substrate.

[0222] According to the Reference Embodiment, a passivation film that can extend the carrier lifetime of a silicon substrate and has a negative fixed charge can be attained at low cost. Further, an application material for forming the passivation film can be provided. Further, a photovoltaic cell element that has the passivation film and exhibits high efficiency can be attained at low cost. Further, a silicon substrate having a passivation film that extends carrier lifetime and has a negative fixed charge can be attained at low cost.

[0223] The passivation film of the present embodiment is a passivation film used for a silicon photovoltaic cell element, and includes aluminum oxide and niobium oxide.

[0224] In the present embodiment, the amount of the fixed charge of the passivation film can be controlled by changing the composition of the passivation film.

[0225] From the viewpoint of stabilizing a negative fixed charge, the mass ratio of niobium oxide and aluminum oxide
is preferably from 30/70 to 80/20. From the viewpoint of further stabilizing a negative fixed charge, the mass ratio of niobium oxide and aluminum oxide is more preferably from 35/65 to 70/30. From the viewpoint of achieving both an improvement in carrier lifetime and a negative fixed charge, the mass ratio of niobium oxide and aluminum oxide is preferably from 50/50 to 90/10.

[0226] The mass ratio of niobium oxide and aluminum oxide in the passivation film can be measured by energy dispersive X-ray spectrometry (EDX), secondary ion mass spectrometry (SIMS) and induced coupled plasma-mass spectrometry (ICP-MS). Specific conditions for the measurement are as follows. A passivation film is dissolved in an acid or an alkaline aqueous solution, and the resulting solution is atomized and introduced in an Ar plasma. Then, a light that is released when an excited element returns to the ground state is dispersed, and its wavelength and intensity are measured. Then, qualitative analysis of the element is performed from the resulting wavelength, and quantitative analysis is performed from the resulting intensity.

[0227] The total content of niobium oxide and aluminum oxide in the passivation film is preferably 80% by mass or more, more preferably 90% by mass or more, from the viewpoint of maintaining favorable properties. The more the content of niobium oxide and aluminum oxide in the passivation film is, the greater the effect of the negative fixed charge.

[0228] The total content of niobium oxide and aluminum oxide in the passivation film can be measured by thermogravimetric analysis, fluorescent X-ray analysis, ICP-MS, and X-ray absorption spectroscopy in combination. Specific conditions for the measurement are as follows. The proportion of an inorganic component is calculated by thermogravimetric analysis, the proportion of niobium and aluminum is calculated by fluorescent X-ray or ICP-MS analysis, and the proportion of an oxide is determined by X-ray absorption spectroscopy.

[0229] From the viewpoint of improving the film quality and adjusting the elasticity, the passivation film may include a component other than niobium oxide and aluminum oxide as an organic component. The existence of an organic component in the passivation film can be confirmed by elemental analysis and FT-IR measurement of the film.

[0230] The content of an organic component in the passivation film is more preferably less than 10% by mass, still more preferably less than 5% by mass or less, and especially preferably 1% by mass or less, in the passivation film.

[0231] The passivation film may be obtained as a thermally-treated product of an application material that includes an aluminum oxide precursor and a niobium oxide precursor. The details of the application material are described below.

[0232] The application material of the present embodiment includes an aluminum oxide precursor and a niobium oxide precursor, and is used for the formation of a passivation film for a photovoltaic cell element having a silicon substrate.

[0233] The aluminum oxide precursor is not particularly limited so long as it can produce an aluminum oxide. As an aluminum oxide precursor, a specific organic aluminum oxide precursor is preferably used in view of dispersing aluminum oxide onto a silicon substrate in a uniform manner, and chemical stability. Examples of the specific organic aluminum oxide precursor include an aluminum triisopropoxide (structural formula: Al(OCH(CH₃)₂)₃, Kojundo Chemical Lab. Co., Ltd., SYM-AL04).

[0234] The niobium oxide precursor is not particularly limited so long as it produces niobium oxide. As a niobium oxide precursor, an organic niobium oxide precursor can be preferably used from the viewpoint of dispersing the niobium oxide precursor onto a silicon substrate in a uniform manner and chemical stability. Examples of the organic niobium oxide precursor include niobium (V) ethoxide (structural formula: Nb(OC₂H₅)₅, molecular weight: 318.21, Kojundo Chemical Lab. Co., Ltd., Nb-05).

[0235] The application material including an organic-based niobium oxide precursor and an organic-based aluminum oxide precursor may be used to obtain a passivation film by forming a film by coating or printing, and removing an organic component by the subsequent thermal treatment (sintering). Therefore, as a result, the passivation film may include an organic component.

<Description of Structure of Photovoltaic Cell Element>

[0236] The structure of a photovoltaic cell element of the embodiment will be illustrated by referring to Figures 12 to 15. Figures 12 to 15 are cross sectional views of first to fourth structural examples in which a passivation film is provided at a back surface of the embodiment.

[0237] Silicon substrate used in this embodiment (a crystalline silicon substrate, a semiconductor substrate) 101 may be either monocrystalline silicon or polycrystalline silicon. Further, silicon substrate 101 may be either crystalline silicon having a p-type conductivity or crystalline silicon having an n-type conductivity. From the viewpoint of exhibiting an effect of the embodiment, a crystalline silicon having a p-type conductivity is more suitable.

[0238] In Figures 12 to 15, an example in which a p-type monocrystalline silicon as silicon substrate 101 is used is illustrated. The type of the monocrystalline silicon or polycrystalline silicon used for silicon substrate 101 is not particularly limited, but a monocrystalline silicon or a polycrystalline silicon having a resistivity of from 0.5 Ω cm to 10 Ω cm is preferred.

[0239] As shown in Figure 12 (first structural example), n-type diffusion layer 102 doped with a V-group element such as phosphorus is formed at a light receiving surface (upper side in the drawing, a first surface) of p-type silicon substrate 101. Then, a pn conjunction is formed between silicon substrate 101 and diffusion layer 102. On a surface of diffusion
layer 102, light receiving surface anti-reflection film 103 such as a silicon nitride (SiN) film, and first electrode 105 (an electrode formed at the light receiving surface, a first electrode, a top electrode or a light receiving surface electrode) of silver (Ag) or the like are formed. Light receiving surface anti-reflection film 103 may function as a passivation film of a light receiving surface. By using a SiN film, the film can function as an anti-reflection film of a light receiving surface and function as a passivation film of a light receiving surface, respectively.

[0240] The photovoltaic cell element of the embodiment may have light receiving surface anti-reflection film 103, or may not. At the light receiving surface of a photovoltaic cell element, it is preferred to form a concave-convex structure (textured structure) in order to reduce the reflectivity at the surface. However, a photovoltaic cell element of the embodiment may not have a textured structure.

[0241] At the back surface (lower side in the drawing, second surface or a back surface) of silicon substrate 101, BSF (Back Surface Field) layer 104, which is a layer doped with a III-group element such as aluminum or boron, is formed. However, the photovoltaic cell element of the embodiment may include BSF layer 104, or may not.

[0242] At the back surface of silicon substrate 101, second electrode 106 (a back surface electrode, a second electrode or a back surface electrode) formed of aluminum or the like is formed in order to achieve a contact (electrical contact) with BSF layer 104 (or the back surface of silicon substrate 101 when BSF layer 104 is not formed).

[0243] In addition, in Figure 12 (first constitutional example), passivation film (a passivation layer) 107 that includes aluminum oxide and niobium oxide is formed at an area excluding a contact region (opening OA) at which BSF layer 104 (or back side surface of the silicon substrate 101 when BSF layer 104 is not formed) and second electrode 106 are electrically connected. Passivation film 107 of the present embodiment may have a negative fixed charge. By this fixed charge, electrons that correspond to minority carriers among those generated in silicon substrate 101 by light are reflected toward the surface side. Therefore, it is expected that a short-circuit current is increased and an incident photon-to-current conversion efficiency is improved.

[0244] Next, a second constitutional example shown in Figure 13 will be explained. In Figure 12 (first constitutional example), second electrode 106 is formed at a contact region (an opening OA) and at an entire area of passivation film 107. In Figure 13 (second constitutional example), second electrode 106 is formed only at a contact region (opening OA). It is also possible that second electrode 106 is formed at a contact region (opening OA) and at a portion of passivation film 107. With the photovoltaic cell element having a constitution shown in Figure 13, a similar effect to the photovoltaic cell element shown in Figure 12 (first constitutional example) can be obtained.

[0245] Subsequently, a third constitutional example shown in Figure 14 will be explained. In the third constitutional example shown in Figure 14, BSF layer 104 is formed only at a portion of a back surface including a contact region (opening OA) with second electrode 106, rather than at an entire area of the back surface as shown in Figure 12 (first constitutional example). A photovoltaic cell element having a constitution as described above (Figure 14) can exhibit a similar effect to the photovoltaic cell element shown in Figure 12 (first constitutional example). Further, in the photovoltaic cell element of the third constitutional example as shown in Figure 14, since the area of BSF layer 104, i.e., the region that is doped with an impurity such as a third group element such as aluminum or boron at a higher concentration than that of silicon substrate 101 is small. Therefore, it is possible to obtain a higher incident photon-to-current conversion efficiency than the photovoltaic cell element shown in Figure 12 (first constitutional example).

[0246] Subsequently, a fourth constitutional example shown in Figure 15 will be explained. In Figure 14 (third constitutional example), second electrode 106 is formed at a contact region (opening OA) and at an entire area of passivation film 107. In Figure 15 (fourth constitutional example), second electrode 106 is formed only at a contact region (opening OA). Second electrode 106 may be formed at the contact region (opening OA) and at a portion of passivation film 107. With a photovoltaic cell element shown in Figure 15, a similar effect to the photovoltaic cell element shown in Figure 14 (third constitutional example) can be obtained.

[0247] In the case in which second electrode 106 is formed at an entire back surface by printing and sintering at high temperature, a convex warpage tends to occur as the temperature decreases. Such a warpage may cause a damage to a photovoltaic cell element and affect the production yield. Further, as the thickness of a silicon substrate becomes smaller, the problem associated with a warpage becomes greater. The warpage is caused by a stress generated by contraction of second electrode 106 including a metal (such as aluminum) that is greater than that of a silicon substrate, which occurs during the temperature decrease because of its greater thermal expansion coefficient than that of the silicon substrate.

[0248] As described above, it is preferred not to form second electrode 106 on an entire area of the back surface, as is shown in Figure 13 (second constitutional example) and Figure 15 (fourth constitutional example), because the electrode structures at the upper and lower sides tend to be symmetry and a stress caused by a difference in the thermal expansion coefficient is less likely to occur. In that case, however, it is preferred to provide an anti-reflection layer.

<Description of method of producing photovoltaic cell element>

[0249] Subsequently, an example of a method for producing a photovoltaic cell element of this embodiment having a
constitution as described above (Figures 12 to 15) will be explained. However, this embodiment is not limited to a photovoltaic cell element that is prepared by the method described below.

[0250] First, a textured structure is formed at a surface of silicon substrate 101, as shown in Figure 12, for example. The textured structure may be formed at both sides of silicon substrate 101, or only at one side (a light receiving surface side) of silicon substrate 101. In order to form a textured structure, silicon substrate 101 is immersed in a heated solution of potassium hydroxide or sodium hydroxide to remove a damaged layer of silicon substrate 101. Subsequently, by immersing silicon substrate 101 in a solution including potassium hydroxide and isopropyl alcohol as major components, a textured structure is formed at both sides or at one side (a light receiving surface side) of silicon substrate 101. As described above, this process may be omitted because the photovoltaic cell element of this embodiment may have a textured structure or may not.

[0251] Subsequently, after washing silicon substrate 101 with a solution of hydrochloric acid, hydrofluoric acid or the like, a phosphorus diffusion layer (n+ layer) is formed as diffusion layer 102 on silicon substrate 101 by performing thermal diffusion of phosphorus oxychloride (POCl₃) or the like. The phosphorus diffusion layer may be formed by, for example, applying an application-type doping material solution containing phosphorus to silicon substrate 101 and performing thermal treatment. After the thermal treatment, by removing the phosphorus glass layer formed at a surface with an acid such as hydrofluoric acid, a phosphorus diffusion layer (n+ layer) is formed as diffusion layer 102. The method of forming a phosphorus diffusion layer is not particularly limited. It is preferred to form a phosphorus diffusion layer such that the depth is in the range of from 0.2 μm to 0.5 μm from the surface of silicon substrate 101, and the sheet resistance is in the range of from 40 Ω/square to 100 Ω/square (ohm/square).

[0252] Subsequently, BSF layer 104 is formed at a back surface by applying an application doping material solution including boron, aluminum or the like at a back surface of silicon substrate 101 and performing thermal treatment. For the application, a method such as screen printing, ink-jetting, dispensing and spin coating may be used. After the thermal treatment, BSF layer 104 is formed by removing a layer of boron glass, aluminum or the like that is formed at the back surface with hydrofluoric acid, hydrochloric acid or the like. The method of forming BSF layer 104 is not particularly limited. Preferably, BSF layer 104 is formed such that the concentration of boron, aluminum or the like is in the range of from 10¹⁸ cm⁻³ to 10²² cm⁻³, and BSF layer 104 is formed in the form of a dot or a line. Since the photovoltaic cell element of this embodiment may include BSF layer 104 or may not, this process may be omitted.

[0253] Further, when both diffusion layer 102 at the light receiving surface, and BSF layer 104 at the back surface are formed with an application solution of a doping material, it is possible to apply the doping material solution onto both sides of silicon substrate 101, form a phosphorus diffusion layer (n+ layer) as diffusion layer 102 and BSF layer 104 at one process, and then remove phosphorus glass, boron glass, or the like formed on the surface at one process.

[0254] Subsequently, a silicon nitride film, which is light receiving surface anti-reflection film 103, is formed on diffusion layer 102. The method of forming light receiving surface anti-reflection film 103 is not particularly limited. It is preferred to form light receiving surface anti-reflection film 103 such that the thickness is in the range of from 50 to 100 nm, and the refractive index is in the range of from 1.9 to 2.2. Light receiving surface anti-reflection film 103 is not limited to a silicon nitride film, and may be a silicon oxide film, an aluminum oxide film, a titanium oxide film or the like. Light receiving surface anti-reflection film 103 such as a silicon nitride film may be formed by plasma CVD, thermal CVD or the like, and is preferably formed by plasma CVD that can be performed at a temperature range of from 350°C to 500°C.

[0255] Subsequently, passivation film 107 is formed at the back surface of silicon substrate 101. Passivation film 107 includes aluminum oxide and niobium oxide, and is formed by, for example, representing an application including an aluminum oxide precursor represented by a metal-organic-decomposition application material that produces aluminum oxide upon thermal treatment (sintering), and a niobium oxide precursor represented by a commercially available metal-organic-decomposition application material, from which niobium oxide is obtained upon thermal treatment (sintering) (a passivation material) and performing thermal treatment (sintering).

[0256] Passivation film 107 may be formed by a process as described below, for example. The application material is applied by spin coating onto one side of a p-type silicon substrate (from 8 1⁄2cm to 12 1⁄2cm) of 8 inches (20.32 cm) with a thickness of 725 μm, from which a spontaneously oxidized film had been removed in advance with hydrofluoric acid at a concentration of 0.049% by mass. Then, the silicon substrate is placed on a hot plate and pre-baked at 120°C for 3 minutes. Subsequently, thermal treatment is performed at 650°C for an hour in a nitrogen atmosphere. In that case, a passivation film including aluminum oxide and niobium oxide is obtained. The film thickness of passivation film 107 formed by the above method as measured with an ellipsometer is generally approximately several ten nm.

[0257] The above application material is applied by printing such as screen printing, offset printing, ink-jet printing, or with a dispenser, in the form of a predetermined pattern including a contact region (opening OA). Passivation film 107 (oxide film) is preferably formed by evaporating a solvent by performing pre-baking to the application material in a temperature range of 80°C to 180°C after application thereof, and performing thermal treatment (annealing) in a nitrogen atmosphere or an air atmosphere at a temperature of from 600°C to 1000°C for approximately 30 minutes to approximately 3 hours.

[0258] Opening (opening for contact) OA is preferably formed on BSF layer 104 in the form of a dot or a line.
Passivation film 107 used for the photovoltaic cell element as described above preferably has a mass ratio of niobium oxide and aluminum oxide (niobium oxide/aluminum oxide) of from 30/70 to 90/10, more preferably from 30/70 to 80/20, even more preferably from 35/65 to 70/30. By satisfying this range, a negative fixed charge can be stabilized. From the viewpoint of attaining both improvement in carrier lifetime and a negative fixed charge, the mass ratio of niobium oxide and aluminum oxide is preferably from 50/50 to 90/10.

Further, passivation film 107 preferably has a total content of niobium oxide and aluminum oxide of 80% by mass or more, more preferably 90% by mass or more.

Subsequently, first electrode 105, which is formed at the light receiving surface side, is formed. First electrode 105 is formed by applying a paste mainly composed of silver (Ag) onto light receiving surface anti-reflection film 103 by screen printing, and performing thermal treatment (fire through). The shape of first electrode 105 may be any form, such as a known shape formed of a finger electrode and a bus bar electrode.

Then, second electrode 106, which is a back surface electrode, is formed. Second electrode 106 may be formed by applying a paste mainly composed of aluminum by screen printing or with a dispenser, and subjecting the paste to thermal treatment. The shape of second electrode 106 is preferably the same shape as that of BSF layer 104, a shape covering the entire back surface, a comb-shape, a lattice-shape, or the like. It is also possible to perform printing of the paste for forming first electrode 105, which is an electrode formed at the light receiving surface side, and perform printing of the paste for forming second electrode 106, and subsequently performing thermal treatment (sintering) to form first electrode 105 and second electrode 106 at one process.

By using a paste mainly composed of aluminum (Al) for the formation of second electrode 106, aluminum diffuses as a dopant and BSF layer 104 is formed at a contact portion of second electrode 106 and silicon substrate 101 by self-aligning. As mentioned previously, BSF layer 104 may be formed separately by applying an application solution of a doping material containing boron, aluminum or the like, and subjecting the same to thermal treatment.

In the above description, although a p-type silicon is used as silicon substrate 101 in the structural and production examples, an n-type silicon may be used as silicon substrate 101. In that case, diffusion layer 102 is formed as a layer doped with a III-group element such as boron, and BSF layer 104 is formed by doping a V-group element such as phosphorus. However, it should be noted that there are cases in which a leakage current flows through a portion at which an inversion layer formed at an interface by a negative fixed charge contacts a metal at the back surface side, and it is difficult to increase conversion efficiency.

In a case in which an n-type silicon substrate is used, passivation film 107 that includes niobium oxide and aluminum oxide can be used at the light receiving surface, as shown in Figure 16. Figure 16 shows a constitutional example of a photovoltaic cell element in which a light receiving surface passivation film of the present embodiment is used.

In that case, diffusion layer 102 formed at the light receiving surface is converted to p-type by doping with boron, and among the generated carriers, holes are collected at the light receiving surface side and electrons are collected at the back surface side. Therefore, passivation film 107, which has a negative fixed charge, is preferably formed at the light receiving surface side.

On the passivation film that includes niobium oxide and aluminum oxide, an anti-reflection film composed of SiN or the like may be further formed by CVD or the like.

In the following, details of the present embodiment will be explained by referring to the Reference Examples and the Comparative Examples.

Passivation material (a-1) as an application material was prepared by mixing 3.0 g of a commercially available metal-organic-decomposition application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass], from which aluminum oxide (Al₂O₃) is obtained upon thermal treatment (sintering) and 3.0 g of a commercially available metal-organic-decomposition application material [Kojundo Chemical Lab. Co., Ltd., Nb-05, concentration: 5% by mass], from which niobium oxide (Nb₂O₅) is produced upon thermal treatment (sintering).

Passivation material (a-1) was applied by spin-coating on one side of a p-type silicon substrate (from 8 Ω·cm to 12 Ω·cm) having a size of 8 inches and 725 μm in thickness, from which a spontaneously oxidized film had been previously removed with hydrofluoric acid at 0.049% by mass concentration, and the silicon substrate was pre-baked on a hot plate at 120°C for 3 minutes. Subsequently, thermal treatment (sintering) was performed under a nitrogen atmosphere at 650°C for an hour, thereby obtaining a passivation film including aluminum oxide and niobium oxide [niobium oxide/aluminum oxide = 68/32 (mass ratio)]. The film thickness as measured with an ellipsometer was 43 nm. As a result of FT-IR measurement of the passivation film, a slight peak derived from an alkyl group was observed at approximately 1,200 cm⁻¹.

Subsequently, a capacitor having a MIS (metal-insulator-semiconductor) structure was prepared by forming plural aluminum electrodes having a diameter of 1 mm on the passivation film by vapor deposition though a metal mask. The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available instrument.
available prober and a commercially available LCR meter (Hewlett-Packard Company, 4275A). As a result, it was found that the flat band voltage (Vfb) shifted from the ideal value of -0.81 V to +0.32 V. From this amount of shift, it was found that the passivation film obtained from passivation material (a-1) exhibited a negative fixed charge at a fixed charge density (Nf) of $-7.4 \times 10^{11}$ cm$^{-2}$.

[0272] In the same manner as the above, passivation material (a-1) was applied onto both sides of an 8-inch p-type silicon substrate. Then, the silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 650°C for an hour, thereby preparing a sample of a silicon substrate having both sides covered with a passivation film. The carrier lifetime of this sample was measured with a lifetime measurement device (Kobelco Research Institute Inc., RTA-540). As a result, the carrier lifetime was 530 μs. For comparison, the carrier lifetime of the same 8-inch p-type silicon substrate, which was passivated by an iodine passivation method, was measured. The result was 1,100 μs.

[0273] From the above description, it was found that a passivation film obtained by thermal treatment (sintering) of the passivation material (a-1) exhibited a certain degree of passivation performance, and had a negative fixed charge.

[Reference Example 1-2]

[0274] In the same manner as Reference Example 1-1, a commercially available metal-organic decomposition application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide (Al$_2$O$_3$) is obtained upon thermal treatment (sintering) and a commercially available metal-organic decomposition application material [Kojundo Chemical Lab. Co., Ltd., Nb-05, concentration: 5% by mass] from which niobium oxide (Nb$_2$O$_5$) is obtained upon thermal treatment (sintering) were mixed at different ratios, and passivation materials (a-2) to (a-7) shown in Table 3 were prepared.

[0275] In the same manner as Reference Example 1-1, a passivation film was prepared by applying each of passivation materials (a-2) to (a-7) onto one side of a p-type silicon substrate, and performing thermal treatment (sintering). The voltage dependency of the electrostatic capacitance of the resulting passivation film was measured, and the fixed charge density was calculated therefrom.

[0276] Further, in the same manner as Reference Example 1-1, a sample was prepared by applying a passivation material onto both sides of a p-type silicon substrate, and performing thermal treatment (sintering). The sample was used for the measurement of carrier lifetime. The results are summarized in Table 3.

[0277] Since passivation materials (a-2) to (a-7) exhibited a certain degree of carrier lifetime after thermal treatment (sintering), although the results were different depending on the ratios of niobium oxide /aluminum oxide (mass ratio) after thermal treatment (sintering), it was suggested that these passivation materials were capable of functioning as passivation films. It was found that all of the passivation films obtained from passivation materials (a-2) to (a-7) exhibited a negative fixed charge in a stable manner, and that the passivation films were suitable for the purpose of passivating a p-type silicon substrate.

[Reference Example 1-3]

[0278] 3.18 g (0.010 mol) of a commercially available niobium (V) ethoxide (structural formula: Nb(OC$_2$H$_5$)$_5$, molecular weight: 318.21) and 1.02 g (0.005 mol) of a commercially available aluminum triisopropoxide (structural formula: Al(OCH(CH$_3$)$_2$)$_3$, molecular weight: 204.25) were dissolved in 80 g of cyclohexane, and passivation material (c-1) at a concentration of 5% by mass was prepared.
Passivation material (c-1) was applied by spin coating on one side of a p-type silicon substrate (from 8 \( \Omega \cdot \text{cm} \) to 12 \( \Omega \cdot \text{cm} \)) having a size of 8 inches and 725 \( \mu \text{m} \) in thickness, from which a spontaneously oxidized film had been previously removed with hydrofluoric acid at 0.049\% by mass concentration, and the silicon substrate was pre-baked on a hot plate at 120\°C for 3 minutes. Subsequently, thermal treatment (sintering) was performed under a nitrogen atmosphere at 600\°C for an hour, thereby obtaining a passivation film including aluminum oxide and niobium oxide. The film thickness as measured with an ellipsometer was 50 nm. As a result of elemental analysis, the ratio Nb/Al/C was 81/14/5 (\% by mass). As a result of FT-IR measurement of the passivation film, a slight peak derived from an alkyl group was observed at approximately 1,200 cm\(^{-1}\).

Subsequently, a capacitor having a MIS (metal-insulator-semiconductor) structure was prepared by forming plural aluminum electrodes having a diameter of 1 mm on the passivation film by vapor deposition through a metal mask. The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available prober and a commercially available LCR meter (Hewlett-Packard Company, 4275A). As a result, it was found that the flat band voltage (V\text{fb}) shifted from the ideal value of -0.81 V to +0.10 V. From this amount of shift, it was found that the passivation film obtained from passivation material (c-1) exhibited a negative fixed charge at a fixed charge density (Nf) of \(-3.2 \times 10^{12} \text{cm}^{-2}\).

In the same manner as the above, passivation material (c-1) was applied onto both sides of an 8-inch p-type silicon substrate, and the silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 600\°C for an hour, and a sample of a silicon substrate having both sides covered with a passivation film was prepared. The carrier lifetime of the sample was measured with a lifetime measurement device (Kobelco Research Institute Inc., RTA-540). As a result, the carrier lifetime was 330 \( \mu \text{s} \). For comparison, the carrier lifetime of the same 8-inch p-type silicon substrate that had been passivated by an iodine passivation method was measured. The result was 1,100 \( \mu \text{s} \).

In view of the above, it was found that a passivation film obtained by performing thermal treatment (sintering) to the passivation material (c-1) exhibited a certain degree of passivation performance and a negative fixed charge.

Passivation material (c-2) was prepared by dissolving 2.35 g (0.0075 mol) of a commercially available niobium (V) ethoxide (structural formula: \( \text{Nb(OCH}_2\text{CH}_3\text{)}_5 \), molecular weight: 318.21), 1.02 g (0.005 mol) of a commercially available aluminum triisopropoxide (structural formula: \( \text{Al(OCH(CH}_3\text{)}_2\text{)}_3 \), molecular weight: 204.25) and 10 g of a novolac resin in 10 g of diethyleneeglycol monobutyl ether acetate and 10 g of cyclohexane.

Passivation material (c-2) was applied by spin coating onto one side of a p-type silicon substrate (from 8 \( \Omega \cdot \text{cm} \) to 12 \( \Omega \cdot \text{cm} \)) having a size of 8 inches and 725 \( \mu \text{m} \) in thickness, from which a spontaneously oxidized film had been previously removed with hydrofluoric acid at 0.049\% by mass concentration. The silicon substrate was pre-baked on a hot plate at 120\°C for 3 minutes. Subsequently, thermal treatment (sintering) was performed under a nitrogen atmosphere at 600\°C for an hour, and a passivation film including aluminum oxide and niobium oxide was prepared. The film thickness as measured with an ellipsometer was 14 nm. As a result of elemental analysis, the ratio Nb/Al/C was 75/17/8 (\% by mass). As a result of FT-IR measurement of a passivation film, a slight peak derived from an alkyl group was observed at approximately 1,200 cm\(^{-1}\).

Subsequently, a capacitor having a MIS (metal-insulator-semiconductor) structure was prepared by forming plural aluminum electrodes having a diameter of 1 mm on the passivation film by vapor deposition through a metal mask. The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available prober and a commercially available LCR meter (Hewlett-Packard Company, 4275A). As a result, it was found that the flat band voltage (V\text{fb}) shifted from the ideal value of -0.81 V to +0.10 V. From this amount of shift, it was found that the passivation film obtained from passivation material (c-2) exhibited a negative fixed charge at a fixed charge density (Nf) of \(-0.8 \times 10^{11} \text{cm}^{-2}\).

In view of the above, passivation material (c-2) was applied on both sides of an 8-inch p-type silicon substrate. The silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 600\°C for an hour, and a sample of a silicon substrate having both sides covered with a passivation film was prepared. The carrier lifetime of the sample was measured with a lifetime measuring assembly (Kobelco Research Institute Inc., RTA-540). As a result, the carrier lifetime was 200 \( \mu \text{s} \). For comparison, the carrier lifetime of the same 8-inch p-type silicon substrate, which was passivated by an iodine passivation method, was measured. The result was 1,100 \( \mu \text{s} \).

In view of the above, it was found that a passivation film obtained by performing thermal treatment (sintering) of passivation material (c-2) exhibited a certain degree of passivation performance and a negative fixed charge.

[Reference Example 1-4]

Passivation material (c-2) was applied by spin coating on one side of a p-type silicon substrate (from 8 \( \Omega \cdot \text{cm} \) to 12 \( \Omega \cdot \text{cm} \)) having a size of 8 inches and 725 \( \mu \text{m} \) in thickness, from which a spontaneously oxidized film had been previously removed with hydrofluoric acid at 0.049\% by mass concentration, and the silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 600\°C for an hour, thereby obtaining a passivation film including aluminum oxide and niobium oxide. The film thickness as measured with an ellipsometer was 50 nm. As a result of elemental analysis, the ratio Nb/Al/C was 81/14/5 (\% by mass). As a result of FT-IR measurement of the passivation film, a slight peak derived from an alkyl group was observed at approximately 1,200 cm\(^{-1}\).
cation material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide (Al₂O₃) is obtained upon thermal treatment (sintering), a commercially available metal-organic decomposition application material [Kojundo Chemical Lab. Co., Ltd., Nb-05, concentration: 5% by mass] from which niobium oxide (Nb₂O₅) is obtained upon thermal treatment (sintering), were mixed at different ratios, and passivation materials (b-1) to (b-7) shown in Table 4 were prepared.

**[0289]** In the same manner as Reference Example 1-1, a passivation film was prepared by applying each of passivation materials (b-1) to (b-7) on one side of a p-type silicon substrate and performing thermal treatment (sintering). By using the passivation film, voltage dependency of the electrostatic capacitance was measured and a fixed charge density was calculated therefrom.

**[0290]** In the same manner as Reference Example 1-1, a sample obtained by applying a passivation material (an application material) on both sides of a p-type silicon substrate and curing the same was used for the measurement of a carrier lifetime. The results are shown in Table 4.

**[0291]** It was found that all of the passivation films obtained from passivation materials (b-1) to (b-6) had a long carrier lifetime and were capable of functioning as a passivation film. In the cases in which niobium oxide / aluminum oxide was 10/90 and 20/80, there was a significant variability among the values of the fixed charge density and a negative fixed charge density was not obtained in a stable manner. However, it was confirmed that a negative fixed charge density could be achieved by using aluminum oxide and niobium oxide. When the measurement was performed by a CV method using a passivation material in which niobium oxide /aluminum oxide was 10/90 and 20/80, the resulting passivation film exhibited a positive fixed charge in some cases, and did not exhibit a negative fixed charge in a stable manner. A passivation film that exhibits positive fixed charge can be used for passivation of an n-type silicon substrate.

**[0292]** On the other hand, a negative fixed charge density could not be obtained from passivation material (b-7) composed of 100% by mass of aluminum oxide.

[Reference Comparative Example 1-2]

**[0293]** As passivation material (d-1), a commercially available metal-organic decomposition application material [Kojundo Chemical Lab. Co., Ltd., Ti-03-P, concentration: 3% by mass] from which titanium oxide (TiO₂) is obtained upon thermal treatment (sintering); as a passivation material (d-2), a commercially available metal-organic decomposition application material [Kojundo Chemical Lab. Co., Ltd., BT-06, concentration: 6% by mass] from which barium titanate (BaTiO₃) is obtained upon thermal treatment (sintering); and as passivation material (d-3), a commercially available metal-organic decomposition application material [Kojundo Chemical Lab. Co., Ltd., Hf-05, concentration: 5% by mass] from which hafnium oxide (HfO₂) is obtained upon thermal treatment (sintering), were prepared.

**[0294]** In the same manner as Reference Example 1-1, each of passivation materials (d-1) to (d-3) was applied on one side of a p-type silicon substrate, and the silicon substrate was subjected to a thermal treatment (sintering) to prepare a passivation film. The passivation film was used for the measurement of voltage dependency of electrostatic capacitance, and a fixed charge density was calculated therefrom.

**[0295]** Moreover, in the same manner as Reference Example 1-1, a passivation material was applied on both sides of a p-type silicon substrate, and the carrier lifetime was measured using a sample obtained by performing thermal treatment (sintering). The results are shown in Table 5.
All of the passivation film obtained from passivation materials (d-1) to (d-3) exhibited a small carrier lifetime, and exhibited an insufficient passivation performance. In addition, these passivation films exhibited a positive fixed charge. A passivation film obtained from passivation material (d-3) exhibited a negative fixed charge, but the value was small. In addition, the carrier lifetime was relatively small, which proved an insufficient function as a passivation film.

A photovoltaic cell element of a structure shown in Figure 14 was prepared using a monocrystalline silicon substrate doped with boron as silicon substrate 101. After performing texture processing to a surface of silicon substrate 101, the application-type phosphorus diffusion material was applied onto a light receiving surface, and diffusion layer 102 (a phosphorus diffusion layer) was formed by performing thermal treatment. Subsequently, the application-type phosphorus diffusion material was removed with dilute hydrofluoric acid.

Subsequently, a SiN film was formed by plasma CVD as light receiving surface anti-reflection film 103 on a light receiving surface. Then, passivation material (a-1) as prepared in Reference Example 1-1 was applied onto a region excluding a contact region (opening OA) at a back surface of silicon substrate 101 by an ink-jet method. Subsequently, passivation film 107 having opening OA was formed by performing thermal treatment.

As a sample, passivation film 107 was prepared, by using passivation material (c-1) prepared in Reference Example 1-3.

Subsequently, on light receiving surface anti-reflection film 103 (SiN film) formed on silicon substrate 101, a paste mainly composed of silver was applied by screen printing in the shape of predetermined finger electrodes and bus bar electrodes. On the back surface, a paste mainly composed of aluminum was applied onto an entire surface by screen printing. Subsequently, thermal treatment (fire through) was performed at 850°C to form an electrode (first electrode 105 and second electrode 106), and BSF layer 104 was formed by allowing aluminum to diffuse in a portion of opening OA at the back surface. A photovoltaic cell element having a structure shown in Figure 14 was thus prepared.

In the aforementioned method, the silver electrode at the light receiving surface was formed by a fire through process without forming an opening in the SiN film. However, it is also possible to form a silver electrode by forming opening OA to the SiN film, and then forming the silver electrode.

For comparison, an aluminum paste was applied onto an entire back surface according to the above preparation process, except that passivation film 107 was not formed. Then, p⁺ layer 114 corresponding to BSF layer 104 and electrode 116 corresponding to second electrode were formed on the entire surface, thereby forming a photovoltaic cell element having a structure shown in Figure 11. With these photovoltaic cell elements, characterization (short-circuit current, open-voltage, fill factor, and conversion efficiency) was performed. The characterization was performed according to JIS-C-8913 (2005) and JIS-C-8914 (2005). The results are shown in Table 6.

From the results shown in Table 6, it was found that a photovoltaic cell element having passivation film 107 including niobium oxide and aluminum oxide exhibited an increased short-circuit current and an increased open voltage, as compared to a photovoltaic cell element not having passivation film 107, and that the conversion efficiency (incident photon-to-current conversion efficiency) was increased by up to 1%.

<Reference Embodiment 2>

[0304] The following are a passivation film, an application material, a photovoltaic cell element and a silicon substrate having a passivation film, according to Reference Embodiment 2.

1. A passivation film including an oxide of at least one vanadium-group element (vanadium-group element oxide) selected from the group consisting of aluminum oxide, vanadium oxide and tantalum oxide, the passivation film being used for a photovoltaic cell element having a silicon substrate.

2. The passivation film according to 1., wherein a mass ratio of the vanadium-group element oxide to the aluminum oxide (vanadium group element oxide / aluminum oxide) is from 30/70 to 90/10.

3. The passivation film according to 1. or 2., wherein a total content of the vanadium-group element oxide and the aluminum oxide is 90% or more.

4. The passivation film according to any one of from 1. to 3., including two or three vanadium-group element oxides selected from the group consisting of vanadium oxide, niobium oxide and tantalum oxide, as the oxide of vanadium-group element.

5. The passivation film according to any one of from 1. to 4., which is a thermally-treated product of an application material that comprises a precursor of at least one vanadium-group element oxide selected from the group consisting of an aluminum oxide precursor, a vanadium oxide precursor and a tantalum oxide precursor.

6. An application material, including a precursor of at least one vanadium-group element oxide selected from the group consisting of an aluminum oxide precursor, a vanadium oxide precursor, and a tantalum oxide precursor, the application material being used for formation of a passivation film of a photovoltaic cell element having a silicon substrate.

7. A photovoltaic cell element, including:

   a p-type silicon substrate;
   an n-type impurity diffusion layer formed at a first surface that is a light receiving surface of the silicon substrate;
   a first electrode formed on the impurity diffusion layer;
   a passivation film that has an opening and is formed on a second surface of the silicon substrate that is opposite to the light receiving surface; and
   a second electrode that is formed on the second surface of the silicon substrate and is electrically connected through the opening of the passivation film to the second surface of the silicon substrate, the passivation film being at least one vanadium-group element oxide selected from the group consisting of aluminum oxide, vanadium oxide and tantalum oxide.

8. The photovoltaic cell element according to 7., including a p-type impurity diffusion layer that is formed on a partial or an entire surface of the second surface of the silicon substrate, and is added with an impurity at a concentration higher than the concentration of the silicon substrate, the second electrode being electrically connected through an opening of the passivation film to the p-type impurity diffusion layer.

9. A photovoltaic cell element, including:

   an n-type silicon substrate;
   a p-type impurity diffusion layer that is formed on a first surface that is a light receiving surface of the silicon substrate;
   a first electrode that is formed on the impurity diffusion layer;
   a passivation film that has an opening and is formed on a second surface of the silicon substrate that is opposite to the light receiving surface; and
   a second electrode that is formed on a second surface of the silicon substrate and is electrically connected through the opening of the passivation film to the second surface of the silicon substrate, the passivation film including at least one vanadium-group element oxide selected from the group consisting of aluminum oxide, vanadium oxide and tantalum oxide.

10. The photovoltaic cell according to 9., including an n-type impurity diffusion layer that is formed on a partial or an entire surface of a second surface of the silicon substrate, and is added with an impurity at a concentration higher than the concentration of the silicon substrate, the second electrode being electrically connected through the opening of the passivation film to the n-type impurity diffusion layer.

11. The photovoltaic cell element according to any one of from 7. to 10., wherein a mass ratio of the vanadium-group element oxide and the aluminum oxide in the passivation film is from 30/70 to 90/10.
<12> The photovoltaic cell element according to any one of from <7> to <11>, wherein a total content of the vanadium-type element oxide and the aluminum oxide in the passivation film is 90% or more.

<13> The photovoltaic cell element according to any one of from <7> to <12>, including two or three vanadium-group element oxides selected from the group consisting of vanadium oxide, niobium oxide, and tantalum oxide as the vanadium-group element oxide.

<14> The silicon substrate having a passivation film, including:

- a silicon substrate; and
- the passivation film for a photovoltaic cell element according to any one of from <1> to <5> which is provided on an entire or partial surface of the silicon substrate.

[0305] According to the Reference Embodiments as described above, a passivation film that can extend the carrier lifetime of a silicon substrate and has a negative fixed charge can be attained at low cost. In addition, an application material that attains formation of the passivation film can be provided. In addition, a photovoltaic cell element that utilizes the passivation film and exhibits high efficiency at low cost can be provided. Moreover, a silicon substrate having a passivation film that extends a carrier lifetime of a silicon substrate and has a negative fixed charge can be attained at low cost.

[0306] The passivation film of the present embodiment is a passivation film used for a silicon photovoltaic cell element, and includes at least one vanadium-group element oxide selected from the group consisting of aluminum oxide, vanadium oxide, and tantalum oxide.

[0307] In addition, in the present embodiment, the amount of a fixed charge of the passivation film can be controlled by changing the composition of the passivation film. A vanadium-group element herein refers to an element that belongs to group 5 in the periodic table, which is selected from vanadium, niobium and tantalum.

[0308] From the viewpoint of being able to stabilize a negative fixed charge, the mass ratio of a vanadium-group element oxide to an aluminum oxide is more preferably from 35/65 to 90/10, further preferably from 50/50 to 90/10.

[0309] The mass ratio of a vanadium-group element oxide to an aluminum oxide in the passivation film can be measured by energy dispersive X-ray spectrometry (EDX), secondary ion mass spectrometry (SIMS) and induced coupled plasma-mass spectrometry (ICP-MS). Specific conditions for the measurement are as follows. A passivation film is dissolved in an acid or an alkaline aqueous solution, and the resulting solution is atomized and introduced in an Ar plasma. The light released when an excited element returns to the ground state is dispersed, and its wavelength and intensity are measured. The resulting wavelength is used for a qualitative analysis of an element, and the resulting intensity is used for quantitative analysis.

[0310] The total content of a vanadium-group element oxide and an aluminum oxide in a passivation film is preferably 80% by mass or more, and more preferably 90% by mass or more from the viewpoint of being able to maintain a favorable property. The more the components other than a vanadium-group element oxide and an aluminum oxide in the passivation film are, the greater the effect of a negative fixed charge is.

[0311] From the viewpoint of improving the film quality and adjusting the elastic modulus, a component other than a vanadium-group element oxide and an aluminum oxide may be included in the passivation film as an organic component. The existence of an organic component in the passivation film can be confirmed by elemental analysis and FT-IR measurement of the film.

[0312] From the viewpoint of obtaining a greater negative fixed charge, vanadium oxide (V_2O_5) is preferably selected as the vanadium-group element oxide.

[0313] The passivation film may include, as a vanadium-group element oxide, two or three kinds of vanadium-group element oxides selected from the group consisting of vanadium oxide, niobium oxide and tantalum oxide.

[0314] The passivation film is preferably obtained by performing thermal treatment of an application material, more preferably obtained by forming a film from an application material by a coating method or a printing method, and performing thermal treatment to remove an organic component from the film. That is, the passivation film may be obtained as a thermally-treated product of an application material that includes an aluminum oxide precursor and a vanadium-group element oxide precursor. Details of the application material will be described below.

[0315] The application material of the present embodiment is an application material used for a passivation film for a photovoltaic cell element having a silicon substrate, and includes a precursor of an aluminum oxide precursor and at least one vanadium-group element oxide precursor selected from a vanadium oxide precursor and a tantalum oxide precursor. As a vanadium-group element oxide precursor included in the application material, a vanadium oxide (V_2O_5) precursor is preferably selected from the viewpoint of a negative fixed charge of a passivation film formed from the applicable material. The application material may include, as a vanadium-group element oxide precursor, two or three kinds of vanadium-group element oxide precursor selected from the group consisting of a vanadium oxide precursor, a niobium oxide precursor and a tantalum oxide precursor.

[0316] The aluminum oxide precursor is not particularly limited so long as it can produce aluminum oxide. From the
viewpoint of dispersing aluminum oxide to a silicon substrate in a uniform manner, and chemical stability, the aluminum oxide precursor is preferably a specific organic aluminum oxide precursor. Examples of a specific organic aluminum oxide precursor include aluminum triisopropoxide (structural formula: Al(OCH(CH₃)₂)₃, Kojundo Chemical Lab. Co., Ltd., SYM-AL04).

[0317] The vanadium-group element oxide precursor is not particularly limited so long as it can produce a vanadium-group element oxide. From the viewpoint of dispersing aluminum oxide to a silicon substrate in a uniform manner, and chemical stability, the vanadium-group element oxide precursor is preferably an organic vanadium-group element oxide precursor.

[0318] Examples of an organic vanadium oxide precursor include vanadium (V) oxytriethoxide (structural formula: VO(OCH₂CH₃)₃, molecular weight: 202.13), Kojundo Chemical Lab. Co., Ltd., V-02. Examples of an organic tantalum oxide precursor include tantalum (V) methoxide (structural formula: Ta(OCH₃)₅, molecular weight: 336.12), Kojundo Chemical Lab. Co., Ltd., Ta-10-P. Example of an organic niobium oxide precursor include niobium (V) ethoxide (structural formula: Nb(OCH₂CH₃)₅, molecular weight: 318.21), Kojundo Chemical Lab. Co., Ltd., Nb-05.

[0319] A passivation film can be obtained by forming a film from the application material that includes an organic vanadium-group element oxide precursor and a specific organic aluminum oxide precursor by a coating method or a printing method, and then performing thermal treatment to remove an organic component from the film. Accordingly, the passivation film may include an organic component. The content of an organic component in the passivation film is more preferably less than 10% by mass, still more preferably 5% by mass or less, and especially preferably 1% by mass or less.

[0320] The photovoltaic cell element (photovoltaic conversion device) of the present embodiment includes a passivation film (an insulating film, a protective insulating film) as described in the above embodiment, i.e., a film including aluminum oxide and at least one vanadium-group element oxide selected from vanadium oxide and tantalum oxide, near a photoelectric interface of a silicon substrate. By including aluminum oxide and at least one vanadium-group element oxide selected from the group consisting of vanadium oxide and tantalum oxide, it is possible to extend a carrier lifetime of a silicon substrate and exhibit a negative fixed charge, thereby improving the properties of a photovoltaic cell element (incident photon-to-current conversion efficiency).

[0321] For the description of the structure and the production method of the photovoltaic cell element according to the present embodiment, the description of the structure of and the production method of the photovoltaic cell element according to Reference Embodiment 1 may be referred to.

[0322] The present embodiments will be hereinafter described in detail by referring to the Reference Examples and the Comparative Examples.

<Vanadium oxide used as vanadium-group element oxide>

[Reference Example 2-1]

[0323] Passivation material (a2-1) as an application material was prepared by mixing 3.0 g of a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide (Al₂O₃) is obtained upon thermal treatment (sintering), and 6.0 g of a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., V-02, concentration: 2% by mass] from which vanadium oxide (V₂O₅) is obtained upon thermal treatment (sintering).

[0324] The passivation material (a2-1) was applied by spin coating on one side of a p-type silicon substrate (from 8 Ω·cm to 12 Ω·cm) having a size of 8 inches and 725 μm in thickness, from which a spontaneously oxidized film had been previously removed with hydrofluoric acid at 0.49% by mass concentration. The silicon substrate was pre-baked on a hot plate at 120°C for 3 minutes. Subsequently, thermal treatment (sintering) was performed under a nitrogen atmosphere at 700°C for 30 minutes, thereby obtaining a passivation film including aluminum oxide and vanadium oxide [vanadium oxide / aluminum oxide = 63/37 (% by mass)]. The film thickness as measured with an ellipsometer was 51 nm. As a result of FT-IR measurement of the passivation film, a slight peak derived from an alkyl group was observed at approximately 1,200 cm⁻¹.

[0325] Subsequently, a capacitor having a MIS (metal-insulator-semiconductor) structure was prepared by forming plural aluminum electrodes having a diameter of 1 mm on the passivation film by vapor deposition through a metal mask. The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available prober and a commercially available LCR meter (Hewlett-Packard Company, 4275A). As a result, it was found that the flat band voltage (Vfb) shifted from the ideal value of -0.81 V to +0.02 V. From this amount of shift, it was found that the passivation film obtained from passivation material (a2-1) exhibited a negative fixed charge at a fixed charge density (Nf) of -5.2 x 10¹¹ cm⁻².

[0326] In a similar manner to the above, passivation material (a2-1) was applied on both sides of an 8-inch p-type silicon substrate, and the silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 650°C for an hour, thereby preparing a sample of a silicon substrate having both sides covered
with a passivation film. The carrier lifetime of the sample was measured with a lifetime measurement device (Kobelco Research Institute Inc., RTA-540). As a result, the carrier lifetime was 400 µs. For comparison, the carrier lifetime of the same 8-inch p-type silicon substrate, which was passivated by an iodine passivation method, was measured. The result was 1,100 µs. Further, the carrier lifetime was measured again after 14 days from the preparation of the sample. The result was 380 µs. From these results, it was found that a decrease in the carrier lifetime (from 400 µs to 380 µs) was less than -10%, indicating that a decrease in carrier lifetime was small.

[0327] In view of the above, it was found that a passivation film obtained by performing thermal treatment (sintering) of passivation material (a2-1) exhibited a certain degree of passivation performance and a negative fixed charge.

[Reference Example 2-2]

[0328] In the same manner as Reference Example 2-1, a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide (Al₂O₃) is obtained upon thermal treatment (sintering), and a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., V-02, concentration: 2% by mass] from which vanadium oxide (V₂O₅) is obtained upon thermal treatment were mixed at different ratios, and passivation materials (a2-2) to (a2-7) as shown in Table 7 were prepared.

[0329] In the same manner as Reference Example 2-1, a passivation film was prepared by applying each of passivation materials (a2-2) to (a2-7) onto one side of a p-type silicon substrate, and subjecting the same to thermal treatment (sintering). The voltage dependency of the electrostatic capacitance of the resulting passivation film was measured, and the fixed charge density was calculated therefrom.

[0330] In addition, in the same manner as Reference Example 2-1, a sample was prepared by applying a passivation material onto both sides of a p-type silicon substrate and performing thermal treatment (sintering), and the carrier lifetime of the sample was measured.

[0331] The obtained results are shown in Table 7. Further, the carrier lifetime was measured again after 14 days from the preparation of the sample. As a result, it was found that a decrease in the carrier lifetime of all of the passivation films obtained from passivation materials (a2-2) to (a2-7) as shown in Table 7 was less than -10%, indicating that the decrease in the carrier lifetime was small.

[0332] From the results that all of passivation materials (a2-2) to (a2-7) showed a negative fixed charge and a certain degree of carrier lifetime after the thermal treatment (sintering), it is suggested that the samples can function as a passivation film, although the results are different depending on the ratio of vanadium oxide / aluminum oxide (mass ratio) after the thermal treatment (sintering). All of the passivation films obtained from passivation materials (a2-2) to (a2-7) exhibited a negative fixed charge in a stable manner, and found to be suitably utilized for passivation of a p-type silicon substrate.

[Reference Example 2-3]

[0333] As a compound from which vanadium oxide (V₂O₅) is obtained upon thermal treatment (sintering), 1.02 g (0.010 mol) of a commercially available vanadium (V) oxytriethoxide (structural formula: VO(OCH₂CH₃)₃, molecular weight: 202.13) and, as a compound from which aluminum oxide (Al₂O₃) is obtained upon thermal treatment (sintering), 2.04 g (0.010 mol) of a commercially available aluminum triisopropoxide (structural formula: Al(OCH(CH₃)₂)₃, molecular weight: 204.25) were dissolved in 60 g of cyclohexane, thereby preparing passivation material (b2-1) at a concentration of 5% by mass.

[0334] Passivation material (b2-1) was applied by spin coating on one side of a p-type silicon substrate (from 8 Ω·cm to 12 Ω·cm) having a size of 8 inches and 725 µm in thickness, from which a spontaneously oxidized film had been
Passivation material (b2-2) was applied by spin coating on one side of a p-type silicon substrate (from 8-inch p-type silicon substrate, which was passivated by an iodine passivation method, was measured. The result was 170 μs. For comparison, the carrier lifetime of the same 8-inch p-type silicon substrate, which was passivated by an iodine passivation method, was measured. The result was 1,100 μs. [0337] In view of the above, it was found that a passivation film obtained by performing thermal treatment (sintering) of passivation material (b2-1) exhibited a certain degree of passivation performance and a negative fixed charge. [Reference Example 2-4]

Passivation material (b2-2) was prepared by dissolving 1.52 g (0.0075 mol) of a commercially available vanadium (V) oxytriethoxide (structural formula: VO(OCH2CH3)3, molecular weight: 202.13), 1.02 g (0.005 mol) of a commercially available aluminum triisopropoxide (structural formula: Al(OCH(CH3)2)3, molecular weight: 204.25) and 10 g of a novolac resin were dissolved in 10 g of diethylene glycol monobutyl ether acetate and 10 g of cyclohexane. The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available prober and a commercially available LCR meter (Hewlett-Packard Company, 4275A). As a result, it was found that the passivation film obtained from passivation material (b2-2) exhibited a negative fixed charge at a fixed charge density (Nf) of -6.2 x 10¹¹ cm⁻². [0336] In the same manner as above, a passivation material (b2-1) was applied on both sides of an 8-inch p-type silicon substrate, and the silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 650°C for an hour, thereby preparing a sample of a silicon substrate having both sides covered with a passivation film. The carrier lifetime of the sample was measured with a lifetime measurement device (Kobelco Research Institute Inc., RTA-540). As a result, the carrier lifetime was 400 μs. For comparison, the carrier lifetime of the same 8-inch p-type silicon substrate, which was passivated by an iodine passivation method, was measured. The result was 1,100 μs. [0335] Subsequently, a capacitor having a MIS (metal-insulator-semiconductor) structure was prepared by forming plural aluminum electrodes having a diameter of 1 mm on the passivation film by vapor deposition through a metal mask. The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available prober and a commercially available LCR meter (Hewlett-Packard Company, 4275A). As a result, it was found that the flat band voltage (Vfb) shifted from the ideal value of -0.81 V to +0.10 V. From this amount of shift, it was found that the passivation film obtained from passivation material (b2-1) exhibited a negative fixed charge at a fixed charge density (Nf) of -2.0 x 10¹¹ cm⁻². [0338] Passivation material (b2-2) was prepared by dissolving 1.52 g (0.0075 mol) of a commercially available vanadium (V) oxytriethoxide (structural formula: VO(OCH2CH3)3, molecular weight: 202.13), 1.02 g (0.005 mol) of a commercially available aluminum triisopropoxide (structural formula: Al(OCH(CH3)2)3, molecular weight: 204.25) and 10 g of a novolac resin were dissolved in 10 g of diethylene glycol monobutyl ether acetate and 10 g of cyclohexane. The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available prober and a commercially available LCR meter (Hewlett-Packard Company, 4275A). As a result, it was found that the flat band voltage (Vfb) shifted from the ideal value of -0.81 V to +0.03 V. From this amount of shift, it was found that the passivation film obtained from passivation material (b2-2) exhibited a negative fixed charge at a fixed charge density (Nf) of -2.0 x 10¹¹ cm⁻². [0340] Subsequently, a capacitor having a MIS (metal-insulator-semiconductor) structure was prepared by forming plural aluminum electrodes having a diameter of 1 mm on the passivation film by vapor deposition through a metal mask. The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available prober and a commercially available LCR meter (Hewlett-Packard Company, 4275A). As a result, it was found that the flat band voltage (Vfb) shifted from the ideal value of -0.81 V to +0.03 V. From this amount of shift, it was found that the passivation film obtained from passivation material (b2-2) exhibited a negative fixed charge at a fixed charge density (Nf) of -2.0 x 10¹¹ cm⁻². [0341] In the same manner as above, a passivation material (b2-2) was applied on both sides of an 8-inch p-type silicon substrate. The silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 650°C for an hour, thereby preparing a sample of a silicon substrate having both sides covered with a passivation film. The carrier lifetime of the sample was measured with a lifetime measurement device (Kobelco Research Institute Inc., RTA-540). As a result, the carrier lifetime was 170 μs. For comparison, the carrier lifetime of the same 8-inch p-type silicon substrate, which was passivated by an iodine passivation method, was measured. The result was 1,100 μs. [0342] In view of the above, it was found that a passivation film obtained by curing the passivation material (b2-2) exhibited a certain degree of passivation performance and a negative fixed charge.
A commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide \((\text{Al}_2\text{O}_3)\) is obtained upon thermal treatment (sintering) and a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., Ta-10-P, concentration: 10% by mass] from which tantalum oxide \((\text{Ta}_2\text{O}_5)\) was obtained upon thermal treatment were mixed at different ratios, and passivation materials (c2-1) to (c2-6) as shown in Table 8 were prepared.

Each of passivation materials (c2-1) to (c2-6) was applied by spin coating on one side of a p-type silicon substrate (from 8 Ω·cm to 12 Ω·cm) having a size of 8 sizes and 725 μm in thickness, from which a spontaneously oxidized film had been previously removed with hydrofluoric acid at 0.49% by mass concentration. The silicon substrate was pre-baked on a hot plate at 120°C for 3 minutes. Subsequently, thermal treatment (sintering) was performed under a nitrogen atmosphere at 700°C for 30 minutes, thereby obtaining a passivation film including aluminum oxide and tantalum oxide. This passivation film was used to measure the voltage dependency of electrostatic capacitance, and the fixed charge density was calculated therefrom.

Subsequently, each of passivation materials (c2-1) to (c2-6) was applied on both sides of an 8-inch p-type silicon substrate, and the silicon substrate was subjected to pre-baking and thermal treatment (sintering) under a nitrogen atmosphere at 650°C for an hour, and a sample of a silicon substrate having both sides covered with a passivation film was prepared. The carrier lifetime of the sample was measured with a lifetime measurement device (Kobelco Research Institute Inc., RTA-540).

The results are shown in Table 8. Further, the carrier lifetime was measured again 14 days after the preparation of the sample. As a result, a decrease in carrier lifetime was less than -10% in all of the passivation films obtained from passivation materials (c2-1) to (c2-6) as shown in Table 8, indicating that a decrease in carrier lifetime is small.

Since all of passivation materials (c2-1) to (c2-6) exhibited a negative fixed charge and a certain level of carrier lifetime after the thermal treatment (sintering), although the results were different depending on the ratio of tantalum oxide / aluminum oxide (mass ratio) after the thermal treatment (sintering), suggesting that they can function as a passivation film.

As a compound from which tantalum oxide \((\text{Ta}_2\text{O}_5)\) is obtained upon thermal treatment (sintering), 1.18 g (0.0025 mol) of a commercially available tantalum (V) methoxide (structural formula: \(\text{Ta}(\text{OCH}_3)_5\), molecular weight: 336.12) and as a compound from which aluminum oxide \((\text{Al}_2\text{O}_3)\) is obtained upon thermal treatment (sintering), 2.04 g (0.010 mol) of a commercially available aluminum triisopropoxide (structural formula: \(\text{Al}(\text{OCH}(\text{CH}_3)_2)_3\), molecular weight: 204.25) were dissolved in 60 g of cyclohexane, and passivation material (d2-1) at a concentration of 5% by mass was prepared.

Passivation material (d2-1) was applied by spin coating on one side of a p-type silicon substrate (from 8 Ω·cm to 12 Ω·cm) having a size of 8 inches and 725 μm in thickness, from which a spontaneously oxidized film had been previously removed with hydrofluoric acid at 0.49% by mass concentration. The silicon substrate was pre-baked on a hot plate at 120°C for 3 minutes. Subsequently, the silicon substrate was subjected to a thermal treatment under a nitrogen atmosphere at 700°C for an hour, thereby obtaining a passivation film including aluminum oxide and tantalum oxide. The film thickness as measured with an ellipsometer was 40 nm. As a result of elemental analysis, the ratio...
with a passivation film. The carrier lifetime of the sample was measured with a lifetime measurement device (Kobelco Nitrogen atmosphere at 600°C for an hour, thereby preparing a sample of a silicon substrate having both sides covered.

In the same manner as the above, passivation material (d2-1) was applied on both sides of an 8-inch p-type silicon substrate, and the silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 600°C for an hour, thereby preparing a sample of a silicon substrate having both sides covered with a passivation film. The carrier lifetime of the sample was measured with a lifetime measurement device (Kobelco Research Institute Inc., RTA-540). As a result, the carrier lifetime was 610 μs. For comparison, the carrier lifetime of the same 8-inch p-type silicon substrate, which was passivated by an iodine passivation method, was measured. The result was 1,100 μs.

In view of the above, it was found that the passivation film obtained by performing thermal treatment to passivation material (d2-1) exhibited a certain level of passivation performance and a negative fixed charge.

[Reference Example 2-7]

[0353] As a compound from which tantalum oxide (Ta2O5) is obtained upon thermal treatment (sintering), 1.18 g (0.005 mol) of a commercially available tantalum (V) methoxide (structural formula: Ta(OCH3)5, molecular weight: 336.12), as a compound from which aluminum oxide (Al2O3) is obtained upon thermal treatment (sintering), 1.02 g (0.005 mol) of a commercially available aluminum triisopropoxide (structural formula: Al(OCH(CH3)2)3, molecular weight: 204.25), and 10 g of a novolac resin were dissolved in a mixture of 10 g of diethylene glycol monobutyl ether acetate and 10 g of cyclohexane, thereby preparing passivation material (d2-2).

[0354] Passivation material (d2-2) was applied by spin coating on one side of a p-type silicon substrate (from 8 Ω·cm to 12 Ω·cm) having a size of 8 inches and 725 μm in thickness, from which a spontaneously oxidized film had been previously removed with hydrofluoric acid at 0.49% by mass concentration. The silicon substrate was pre-baked on a hot plate at 120°C for 3 minutes. Subsequently, thermal treatment was performed under a nitrogen atmosphere at 650°C for an hour, thereby obtaining a passivation film including aluminum oxide and tantalum oxide. The film thickness as measured with an ellipsometer was 18 nm. As a result of elemental analysis, it was found that the ratio Ta/Al/C was 75/22/3 (wt%). As a result of FT-IR measurement of the passivation film, a slight peak derived from an alkyl group was observed at approximately 1200 cm⁻¹.

[0355] Subsequently, a capacitor having a MIS (metal-insulator-semiconductor) structure was prepared by forming plural aluminum electrodes having a diameter of 1 mm on the passivation film through a metal mask. The voltage dependency of electrostatic capacitance (C-V property) of the capacitor was measured with a commercially available LCR meter (Hewlett-Packard Company, 4275A). As a result, it was found that the flat band voltage (Vfb) shifted from the ideal value of -0.81 V to -0.43 V. From this amount of shift, it was found that the passivation film obtained from passivation material (d2-1) exhibited a negative fixed charge at a fixed charge density (Nf) of -5.5 x 10¹⁰ cm⁻².

[0356] In the same manner as the above, the passivation material (d2-2) was applied on both sides of an 8-inch p-type silicon substrate. The silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 600°C for an hour, thereby preparing a sample of a silicon substrate having both sides covered with a passivation film. The carrier lifetime of the sample was measured with a lifetime measurement device (Kobelco Research Institute Inc., RTA-540). As a result, the carrier lifetime was 250 μs. For comparison, the carrier lifetime of the same 8-inch p-type silicon substrate, which was passivated by an iodine passivation method, was measured. The result was 1,100 μs.

In view of the above, it was found that the passivation film obtained by performing thermal treatment (sintering) of passivation material (d2-2) exhibited a certain level of passivation performance and a negative fixed charge.

<Combination use of two or more vanadium-group element oxides>

[Reference Example 2-8]

[0358] A commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide (Al₂O₃) is obtained upon thermal treatment (sintering), a
commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., V-02, concentration: 2% by mass] from which vanadium oxide (V$_2$O$_5$) is obtained upon thermal treatment (sintering) and a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., Ta-10-P, concentration: 10% by mass] from which tantalum oxide (Ta$_2$O$_5$) is obtained upon thermal treatment (sintering) were mixed to produce passivation material (e2-1) as an application material (see Table 9).

[0359] A commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide (Al$_2$O$_3$) is obtained upon thermal treatment (sintering), a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., V-02, concentration: 2% by mass] from which vanadium oxide (V$_2$O$_5$) is obtained upon thermal treatment (sintering) and a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., Nb-05, concentration: 5% by mass] from which niobium oxide (Nb$_2$O$_5$) is obtained upon thermal treatment (sintering) were mixed, thereby preparing passivation material (e2-2) as an application material (see Table 9).

[0360] A commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide (Al$_2$O$_3$) is obtained upon thermal treatment (sintering), a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., Ta-10-P, concentration: 10% by mass] from which tantalum oxide (Ta$_2$O$_5$) is obtained upon thermal treatment (sintering) and a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., Nb-05, concentration: 5% by mass] from which niobium oxide (Nb$_2$O$_5$) is obtained upon thermal treatment (sintering) were mixed, thereby preparing a passivation material (e2-3) as an application material (see Table 9).

[0361] A commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide (Al$_2$O$_3$) is obtained upon thermal treatment (sintering), a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., V-02, concentration: 2% by mass] from which vanadium oxide (V$_2$O$_5$) is obtained upon thermal treatment (sintering), a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., Ta-10-P, concentration: 10% by mass] from which tantalum oxide (Ta$_2$O$_5$) is obtained upon thermal treatment (sintering) and a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., Nb-05, concentration: 5% by mass] from which niobium oxide (Nb$_2$O$_5$) is obtained upon thermal treatment (sintering) were mixed, thereby preparing passivation material (e2-4) as an application material (see Table 9).

[0362] In the same manner as Reference Example 2-1, each of passivation materials (e2-1) to (e2-4) was applied by spin coating on one side of a p-type silicon substrate (from 8 Ω·cm to 12 Ω·cm) having a size of 8 inches and 725 μm in thickness from which a spontaneously oxidized film had been removed with hydrofluoric acid at a concentration of 0.49% by mass, and the silicon substrate was pre-baked on a hot plate at 120°C for 3 minutes. Subsequently, the silicon substrate was subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 650°C for an hour, thereby obtaining a passivation film including aluminum oxide and two or more kinds of vanadium-group element oxides.

[0363] With the passivation film obtained above, the voltage dependency of electrostatic capacitance was measured and the fixed charge density was calculated therefrom.

[0364] Subsequently, each of passivation materials (e2-1) to (e2-4) was applied on both sides of a 8-inch p-type silicon substrate, and the silicon substrate was pre-baked and subjected to a thermal treatment (sintering) under a nitrogen atmosphere at 650°C for an hour, thereby preparing a sample of a silicon substrate having both sides covered with a passivation film. The carrier lifetime of the sample was measured with a lifetime measurement device (Kobelco Research Institute Inc., RTA-540).

[0365] The results are shown in Table 9.

[0366] All of the passivation films obtained from passivation materials (e2-1) to (e2-4) exhibited a negative fixed charge after performing thermal treatment (sintering) and a certain degree of carrier lifetime, although the results were different depending on the ratio (mass ratio) of the two or more kinds of vanadium-group element oxides to aluminum oxide after the thermal treatment (sintering), suggesting that they can function as a passivation film.

In the same manner as Reference Example 2-1, a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., SYM-AL04, concentration: 2.3% by mass] from which aluminum oxide ($\text{Al}_2\text{O}_3$) is obtained upon thermal treatment (sintering), a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., V-02, concentration: 2% by mass] from which vanadium oxide ($\text{V}_2\text{O}_5$) is obtained upon thermal treatment (sintering) and a commercially available organic metal film application material [Kojundo Chemical Lab. Co., Ltd., Ta-10-P, concentration: 10% by mass] from which tantalum oxide ($\text{Ta}_2\text{O}_5$) is obtained upon thermal treatment (sintering) were mixed, thereby preparing passivation materials (f2-1) to (f2-8) as an application material (see Table 10).

Further, passivation material (f2-9) in which aluminum oxide was used alone was prepared (see Table 10).

In the same manner as Reference Example 2-1, each of passivation materials (f2-1) to (f2-9) was applied on one side of a p-type silicon substrate, and the silicon substrate was subjected to a thermal treatment (sintering) to prepare a passivation film. With the passivation film, the voltage dependency of electrostatic capacitance was measured and the fixed charge density was calculated therefrom.

Further, in the same manner as Reference Example 2-1, each of passivation materials (f2-1) to (f2-9) was applied on both sides of a p-type silicon substrate, and the silicon substrate was subjected to a thermal treatment (sintering), thereby preparing a sample. The carrier lifetime of the sample was measured, and the results are shown in Table 10.

As shown in Table 10, in the cases in which aluminum oxide / vanadium oxide or tantalum oxide of the passivation material is 90/10 and 80/20, there was a significant variability among fixed charge density values, and a negative fixed charge density could not be obtained in a stable manner. However, it was determined that a negative fixed charge density could be attained by using aluminum oxide and niobium oxide. When the measurement was performed by a CV method in the cases in which aluminum oxide / vanadium oxide or tantalum oxide of the passivation material was 90/10 and 80/20 by a CV method, the passivation film exhibited a positive fixed charge in some cases and did not exhibit a negative fixed charge in a stable manner. A passivation film that exhibits positive fixed charge can be used as a passivation film for an n-type silicon substrate. On the other hand, a negative fixed charge density could not be obtained with passivation material (f2-9) including 100% by mass of aluminum oxide.

A photovoltaic cell element having a structure shown in Figure 14 was prepared by using as silicon substrate 101, a monocrystalline silicon substrate doped with boron. The surface of silicon substrate 101 was subjected to texture processing, and an application-type phosphorus diffusion material was applied only onto a light receiving surface, and diffusion layer 102 (a phosphorus diffusion layer) was formed by performing thermal treatment. Thereafter, the application-type phosphorus diffusion material was removed with dilute hydrofluoric acid.

Subsequently, at the light receiving surface side, a SiN film was formed by plasma CVD as light receiving surface anti-reflection film 103. Then, passivation material (a2-1) as prepared in Reference Example 2-1 was applied by an ink jet method to a region excluding a contact region (opening OA) at the back surface side of silicon substrate.
101. Thereafter, thermal treatment was performed to form passivation film 107 having opening OA. A sample in which passivation film 107 was formed from passivation material (c2-1) as prepared in Reference Example 2-5 was also prepared.

[0374] Subsequently, a paste mainly composed of silver was applied by screen printing in the form of predetermined finger electrodes and bus bar electrodes, on light receiving surface anti-reflection film 103 (SiN film) formed on the light receiving surface of silicon substrate 101. At the back surface side, a paste mainly composed of aluminum was applied by screen printing on an entire surface. Thereafter, thermal treatment (fire through) was performed at 850°C to form an electrode (first electrode 105 and second electrode 106), and BSF layer 104 was formed by allowing aluminum to diffuse in opening OA, thereby forming a photovoltaic cell element having a structure shown in Figure 14.

[0375] Although the method of forming a silver electrode at the light receiving surface as described herein includes a fire-through process without forming an opening to the SiN film, it is also possible to form a silver electrode by a method in which opening OA is formed to the SiN film by etching or the like, and subsequently the silver electrode is formed.

[0376] For comparison, a photovoltaic cell element having a structure shown in Figure 11 was prepared by a method as described above, except that passivation film 107 was not formed and an aluminum paste was applied on an entire region of the back surface, and p⁺ layer 114 corresponding to BSF layer 104 and electrode 116 corresponding to the second electrode were formed on the entire region of the back surface. With these photovoltaic cell elements, characterization (short-circuit current, open-voltage, fill factor and conversion efficiency) was performed. The characterization was performed according to JIS-C-8913 (2005) and JIS-C-8914 (2005). The results are shown in Table 11.

[0377] From the results shown in Table 11, it was found that the photovoltaic cell element having passivation film 107 exhibited an increase in short-circuit current and open voltage, as compared with a photovoltaic cell element not having passivation film 107. In addition, it was found that the photovoltaic cell element having passivation film 107 exhibited an improved conversion efficiency (incident photon-to-current conversion efficiency) by up to 0.6%.

Claims

1. A composition for forming a passivation layer, comprising a resin and a compound represented by the following Formula (I):

   \[ M(OR_1)^m \]  

   (I)

   wherein, in Formula (I), M comprises at least one metal element selected from the group consisting of Nb, Ta, V, Y and Hf, each \( R_1 \) independently represents an alkyl group having from 1 to 8 carbon atoms or an aryl group having from 6 to 14 carbon atoms, and m represents an integer from 1 to 5.

2. The composition for forming a passivation layer according to claim 1, further comprising a compound represented by the following Formula (II):
wherein, in Formula (II), each $R^2$ independently represents an alkyl group having from 1 to 8 carbon atoms, $n$ represents an integer from 0 to 3, each of $X^2$ and $X^3$ independently represents an oxygen atom or a methylene group, and each of $R^3$, $R^4$ and $R^5$ independently represents a hydrogen atom or an alkyl group having from 1 to 8 carbon atoms.

3. The composition for forming a passivation layer according to claim 1 or 2, wherein a content of the resin is from 0.1% by mass to 50% by mass.

4. The composition for forming a passivation layer according to claim 2 or 3, wherein, in Formula (II), each $R^2$ independently represents an alkyl group having from 1 to 4 carbon atoms.

5. The composition for forming a passivation layer according to any one of claims 2 to 4, wherein, in Formula (II), $n$ represents an integer from 1 to 3, and each $R^5$ independently represents an alkyl group having from 1 to 4 carbon atoms.

6. A semiconductor substrate having a passivation layer, comprising:
   a semiconductor substrate; and
   a passivation layer that is a thermally-treated product of the composition for forming a passivation layer according to any one of claims 1 to 5 and that is provided at an entire or partial surface of the semiconductor substrate.

7. A method of producing a semiconductor substrate having a passivation layer, the method comprising:
   a process of forming a composition layer by applying the composition for forming a passivation layer according to any one of claims 1 to 5 onto an entire or partial surface of a semiconductor substrate; and
   a process of forming a passivation layer by subjecting the composition layer to a thermal treatment.

8. A photovoltaic cell element, comprising:
   a semiconductor substrate having a pn junction of a p-type layer and an n-type layer that are connected;
   a passivation layer that is a thermally-treated product of the composition for forming a passivation layer according to any one of claims 1 to 5 and that is provided at an entire or partial surface of the semiconductor substrate; and
   an electrode provided at at least one layer selected from the group consisting of the p-type layer and the n-type layer.

9. A method of producing a photovoltaic cell element, the method comprising:
   a process of forming a composition layer by applying the composition for forming a passivation layer according to any one of claims 1 to 5 onto a surface of one side or both sides of a semiconductor substrate, the semiconductor substrate having a pn junction of a p-type layer and an n-type layer that are connected and an electrode on one or more layers selected from the group consisting of the p-type layer and the n-type layer;
   a process of forming a passivation layer by subjecting the composition layer to a thermal treatment.
10. A photovoltaic cell, comprising:

the photovoltaic cell element according to claim 8; and

a wiring material provided on the electrode of the photovoltaic cell element.
**INTERNATIONAL SEARCH REPORT**

**A. CLASSIFICATION OF SUBJECT MATTER**

H01L21/316(2006.01)i, C09K3/00(2006.01)i, H01L21/312(2006.01)i, H01L31/04(2006.01)i

According to International Patent Classification (IPC) or to both national classification and IPC

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)

H01L21/316, C09K3/00, H01L21/312, H01L31/04

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Jitsuyo Shinan Koho 1922-1996 Jitsuyo Shinan Toroku Koho 1996-2013

Kokai Jitsuyo Shinan Koho 1971-2013 Toroku Jitsuyo Shinan Koho 1994-2013

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

<table>
<thead>
<tr>
<th>Category*</th>
<th>Citation of document, with indication, where appropriate, of the relevant passages</th>
<th>Relevant to claim No.</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>JP 2000-294817 A (Daipinpon Printing Co., Ltd.), 20 October 2000 (20.10.2000), paragraphs [0019] to [0027], [0041] to [0042]; fig. 5 (Family: none)</td>
<td>1-4, 6, 8, 10, 1-10</td>
</tr>
</tbody>
</table>

Further documents are listed in the continuation of Box C. See patent family annex.

* Special categories of cited documents:
  * A*: document defining the general state of the art which is not considered to be of particular relevance
  * E*: earlier application or patent but published on or after the international filing date
  * L*: document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
  * O*: document referred to in oral proceedings
  * P*: document published prior to the international filing date but later than the priority date claimed
  * T*: later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
  * X*: document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
  * Y*: document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is considered together with one or more other documents such combination being obvious to person skilled in the art
  * Z*: document member of the same patent family

**Date of the actual completion of the international search**

08 October, 2013 (08.10.13)

**Date of mailing of the international search report**

22 October, 2013 (22.10.13)

**Name and mailing address of the ISA**

Japanese Patent Office

**Form PCT/ISA/210 (second sheet) (July 2009)**
