Note: Within nine months of the publication of the mention of the grant of the European patent in the European Patent Bulletin, any person may give notice to the European Patent Office of opposition to that patent, in accordance with the Implementing Regulations. Notice of opposition shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).
Description

CROSS REFERENCE

FIELD OF THE INVENTION

[0001] The field of the invention is nanoparticles for use in cosmetic, diagnostic and/or therapeutic procedures.

BACKGROUND OF THE INVENTION

[0002] Laser treatments of the skin are widely known and have been highly touted for therapeutic and cosmetic utility. Therapeutically, potential uses for laser skin therapy include laser ablation of cancerous cells in cancer patients and laser ablation of damaged tissue in burn victims. Cosmetic applications for laser skin therapy are much more numerous, and include hair removal/reduction, treatment of dyschromia, shrinking of the skin following operations such as liposuction, acne treatment, chemical or physical ablation of unwanted markings on the skin, surgical treatments including nose reduction and face- and neck-lifts, and other aesthetic skin remodeling purposes. See e.g. US 2005/203495 A1, WO 2009/124189 A1 and WO 2006/051542 A1 as exemplary prior art dealing with methods involving plasmonic particles.

SUMMARY OF THE INVENTION

[0003] Despite the promise of laser therapy for skin therapies and cosmetics, current laser procedures have limited efficacy, requiring prohibitive numbers of repeated treatments and driving increased costs. Suboptimal laser treatments also have limited specificity, resulting in debilitating clinical side effects, such as non-specific skin damage, skin irritation and scarring.

[0004] Light-based hair removal systems suffer from particularly low rates of efficacy at removing light hair (vellus, blonde, gray, red hair). Multiple (even 6 or more) treatments are insufficient to achieve a therapeutic result in blonde-gray- or red-haired patients, even with the use of topically applied chromophores such as carbon. In addition to light hair removal, thermoablative technology has untapped potential in the fields of wound healing, tissue remodeling, vascular repair, and acne treatment.

[0005] Acne vulgaris results from obstruction of the pilosebaceous unit, consisting of the hair shaft, hair follicle, sebaceous gland and erector pili muscle, which leads to accumulation of sebum oil produced from the sebaceous gland and the subsequent colonization of bacteria within the follicle. Microcomedones formed as a result of accumulated sebum progress to non-inflamed skin blemishes (white/blackheads), or to skin blemishes which recruit inflammatory cells and lead to the formation of papules, nodules and pus-filled cysts. The sequelae of untreated acne vulgaris often include hyperpigmentation, scarring and disfiguration, as well as significant psychological distress. Therefore, acne treatments seek broadly to reduce the accumulation of sebum and microorganisms within follicles and the sebaceous gland.

[0006] Methods involving light and lasers are promising for the treatment skin disorders, but are still insufficiently effective. Ultraviolet (UV)/blue light is approved by the FDA for the treatment of mild to moderate acne only, due to its anti-inflammatory effects mediated on skin cells (keratinocytes), potentially through the action of endogenous porphyrin photosensitzers within follicles. Exogenous porphirin precursors such as 5-aminoluveulinic acid (5-ALA) have been formulated for topical or oral delivery and shown to accumulate within sebaceous follicles, absorb photons from red light exposure and form reactive oxygen species that directly damage cellular membranes and proteins. This procedure combining porphyrin application and high intensity red light, termed 'photodynamic therapy', has been demonstrated to reduce sebum production and acne by 50% for 20 weeks post-irradiation. However, high intensity energies (50-150 J/cm²) are required to damage sebaceous gland skin structures, and transdermal porphyrin penetration leads to off-target side-effects which include sensitivity to light, pain, inflammation, hyper/hypo-pigmentation, and permanent scarring.

[0007] For laser therapy to achieve its full utility in the treatment of human skin disorders, methods to locally induce photo-destruction in skin structures without affecting surrounding tissues must be achieved.

[0008] Provided herein, in certain embodiments, are new compositions and methods useful in the targeted thermo-modulation of target cell populations and target tissues, for the purposes of cosmetic treatments and the treatment and prevention of chronic and acute diseases and disorders.

[0009] In one aspect, described herein are compositions of matter. For example, in one embodiment, provided is a composition comprising a cosmetically acceptable carrier and a plurality of plasmonic nanoparticles in an amount effective to induce thermomodulation in a target tissue region with which the composition is topically contacted.

[0010] In some embodiments, the composition comprises plasmonic nanoparticles that are activated by exposure to energy delivered from a nonlinear excitation surface plasmon resonance source to the target tissue region. In further or additional embodiments, described herein are compositions comprising at least one plasmonic nanoparticle that comprises a metal, metallic composite, metal oxide, metallic salt, electric conductor, electric superconductor, electric sem-
iconductor, dielectric, quantum dot or composite from a combination thereof. In further or additional embodiments, provided herein is a composition wherein a substantial amount of the plasmonic particles present in the composition comprise geometrically-tuned nanostructures. In certain embodiments, provided herein is a composition wherein plasmonic particles comprise any geometric shape currently known or to be created that absorb light and generate plasmon resonance at a desired wavelength, including nanoplates, solid nanoshells, hollow nanoshells, nanorods, nanorice, nanospheres, nanofibers, nanowires, nanoprisms, nanostars or a combination thereof. In yet additional embodiments, described herein is a composition wherein the plasmonic particles comprise silver, gold, nickel, copper, titanium, silicon, galadium, palladium, platinum, or chromium.

[BRIEF DESCRIPTION OF FIGURES]

Figure 1 is illustrative of schematics depicting certain embodiments of the use of formulations for hair removal and acne treatment. Depicted is (A) for hair removal, the plasmonic nanoparticle formulation (black) is 1. applied topically to human skin, 2. delivered deep into the follicle and washed from the skin surface, 3. irradiated with a clinical laser or dermabrasion, or a combination thereof. In still further embodiments, provided is a method wherein the irradiation comprises light having a wavelength between about 200 nm and about 10,000 nm, a fluence of about 1 to about 100 joules/cm², a pulse width of about 1 femtosecond to about 1 second, and a repetition frequency of about 1 Hz to about 1 THz.

In further or additional embodiments, described herein is a composition wherein a substantial amount of the plasmonic particles present in the composition comprises water and propylene glycol.

In yet another embodiment, the solvent is selected from the group consisting of water, propylene glycol, alcohol, hydrocarbon, chloroform, acid, base, acetone, diethyl-ether, dimethyl sulfoxide, dimethylformamide, acetonitrile, tetrahydrofuran, dichloromethane, and ethylacetate. In one embodiment, the composition comprises plasmonic particles that have an optical density of at least about 1 O.D. at one or more peak resonance wavelengths.

In further or additional embodiments, described herein is a composition wherein plasmonic particles comprise any geometric shape currently known or to be created that absorb light and generate plasmon resonance at a desired wavelength, including nanoplates, solid nanoshells, hollow nanoshells, nanorods, nanorice, nanospheres, nanofibers, nanowires, nanoprisms, nanostars or a combination thereof. In yet additional embodiments, described herein is a composition wherein the plasmonic particles comprise silver, gold, nickel, copper, titanium, silicon, galadium, palladium, platinum, or chromium.
at a wavelength resonant to the peak absorption wavelength of the plasmonic particle, and 4. shed from the follicle
along with the damaged hair follicle; and (B) for acne treatment, the plasmonic nanoparticle formulation (black) is
1. applied topically to human skin, 2. delivered specifically into the sebaceous gland and washed from the skin
surface, 3. irradiated with a clinical laser at a wavelength resonant to the peak absorption wavelength of the plasmonic
particle, and 4. shed from the target site where the accumulated sebum and sebum-producing capabilities of the
sebaceous gland are destroyed.

Figure 2 is illustrative of a temperature profile of certain embodiments of the formulations of plasmonic nanoparticles
(SL-001, triangles) provided herein compared to exemplary current clinical dyes carbon lotion (circles), meladine
spray (diamonds), and indocyanine green (squares), after exposure to 1064 nm, 20 J/cm², 55 ms laser pulses. SL-
001 and dyes were equally diluted at 1:1000 from clinical concentration (SL-001 1000 O.D., carbon 20-200 mg/ml,
meladine 1 mg/ml, ICG 5 mg/ml). n=3, error S.D. of mean.

Figure 3 is illustrative of hair follicle penetration of fluorescently-labeled nanoparticles determined using porcine skin
explants and confocal imaging of certain embodiments of the subject matter described herein. Depicted is (A)
schematic of treated porcine skin, sectioned and imaged at an angle to the follicle, in two serial 60 µm planes: ‘plane
1’ (showing follicle infundibulum) and ‘plane 2’ (showing deep follicle); (B) representative confocal images show red
fluorescent nanoparticles (548 nm) within superficial and deep follicle, but not in underlying dermis; and (C) red
fluorescent nanoparticles retained in the deep follicle (~400 µm) at high magnification. Green is tissue autofluores-
cence.

Figure 4 is illustrative of a hair follicle penetration of plasmonic nanoparticles determined using porcine skin explants
and dark field imaging. Shown is (A) schematic of treated porcine skin, sectioned and imaged horizontal to the
follicle; (B) bright blue plasmonic particles are visible in a 1.2 mm deep section, and are differentiated from (C)
untreated (negative control) porcine skin, where no pigments are visible.

Figure 5 depicts clinical observations in live human skin treated with Laser Only (left forearm) or Plasmonic Particles
+ Laser (right forearm) demonstrates non-specific and specific photothermal damage. (A,B) In the top panel, human
skin was irritated with 810 nm laser pulses (30 J/cm², 30 ms, 3 passes) alone (A), or after treatment with a
formulation of 830 nm resonant, Uncoated plasmonic nanoparticles in 20% propylene glycol (B). The plasmonic
nanoparticle formulation was applied with 3 minute massage, and the skin surface wiped with 3 applications of
alternative water and ethanol before laser irradiation. At 30 minutes following laser irradiation, non-specific clinical
burns were observed in B compared to A, due to significant photothermal heating of residual, Uncoated particles
on the skin surface. (C,D) In the bottom panel, human skin was irradiated with 1064 nm laser pulses (40 J/cm², 55
ms, 3 passes) alone (C), or after treatment with a formulation of 1020 nm resonant, Silica-coated plasmonic nano-
particles in 20% propylene glycol (D). The plasmonic nanoparticle formulation was applied with 3 minute massage,
and the skin surface wiped with 3 applications of alternative water and ethanol before laser irradiation. At 30 minutes
following laser irradiation, no evidence of burning of the skin or erythema was observed in D or C, as Silica-coated
particles could be sufficiently wiped from the skin surface. Magnified photography of D showed specific photothermal
damage (perifollicular erythema and edema) in the nanoparticle-targeted site.

Figure 6 is a photograph showing nanoparticle-targeted photothermal damage in live human skin treated with a
plasmonic nanoparticle formulation and clinical laser. A formulation of 1020 nm resonant, silica-coated (200 nm-
diameter) plasmonic nanoparticles in 20% propylene glycol and 3 minute massage was contacted with live human
skin. The procedure was repeated 3 times, and skin surface wiped with 3 applications of alternating water and
ethanol to remove residual particles. The treated skin was irradiated with 1064 nm laser pulses (40 J/cm², 55 ms,
3 passes). Following laser irradiation, clinical observation of perifollicular erythema and edema was visible at hair
folicies where nanoparticles were targeted, but not visible in surrounding or non-particle-treated tissues.

Figure 7 is illustrative of a plasmonic nanoparticle formulation delivery to human skin sebaceous gland. (A) Confocal
microscope image of a human skin biopsy and section, immunostained for Collagen IV basement membrane (blue)
and PGP 9.5 nerve marker (green), shows hair follicle (HF) and sebaceous gland (SG) microanatomy. Red is silica
nanoparticles (200nm). (B) Schematic and dark field microscope image of excised human skin treated with plasmonic
nanoparticle formulation, then sectioned and imaged horizontal to the follicle. Bright blue plasmonic particles are
visible up to 400 µm deep and within the human sebaceous gland.

Figure 8 is illustrative of cosmetic formulations of plasmonic nanoparticles for sebaceous gland targeting that include
surfactants. Silica-coated nanoparticles (200 nm diameter, 100 O.D.) were formulated in 20% propylene glycol with
the addition of surfactants sodium dodecyl sulfate (SDS) or sodium laureth-2 sulfate (SLES), applied to human skin
with massage + ultrasound, and skin was sectioned in horizontal planes for dark field microscopy. (A) Formulations
of plasmonic particles in 1% SDS/20% PG penetrated sebaceous gland down to 400 um as in Figure 7. (B) Formu-
lations of plasmonic particles in 1% SLES/20% PG penetrated sebaceous gland down to 600 um. Inset shows a
skin section without visible particles (scale bar 40 um). Sebaceous gland is pseudo-outlined.

Figure 9 is an image depicting impact of massage vs. ultrasound on nanoparticle targeting to the human follicle and
sebaceous gland. Silica-coated nanoparticles (200 nm diameter, 100 O.D.) were formulated in 1% SDS/20% pro-
pylene glycol and applied to human skin with massage or ultrasound. Dark field images of horizontal planar sections taken at low (20x) and high (50x) magnification show (A) little to no accumulation of plasmonic particles into follicle infundibulum after massage alone, compared to (B) follicle infundibulum expansion and significant plasmonic particle accumulation after ultrasound alone. Figure 10 depicts an embodiment of the plasmonic nanoparticle cosmetic formulations for sebaceous gland targeting. Plasmonic nanoparticles comprising different shapes and coatings were formulated in 1% SDS/20% propylene glycol and applied to human skin with massage + ultrasound, and skin was sectioned in horizontal planes for dark field microscopy. (A) Polyethylene glycol (PEG)-coated nanorods (gold, 15 x 30 nm dimension) were observed within the follicle infundibulum up to 200 um deep (white arrow). (B) Lower concentration (10 O.D.) Silica-coated nanoplates (silver, 200 nm diameter) were observed up to 600 um deep in the follicle and in the sebaceous gland (open arrow). Inset shows skin sections without visible particles (scale bar 100 um).

DETAILED DESCRIPTION OF THE INVENTION

[0017] The biology of physiological and pathophysiological tissue growth and remodeling, and alterations in cell morphology is more complex than generally appreciated, involving an interacting network of biological compounds, physical forces, and cell types.

[0018] An object of the subject matter described herein is to provide compositions, methods and systems for noninvasive and minimally-invasive treatment of skin and underlying tissues, or other accessible tissue spaces with the use of nanoparticles. The treatment includes, but is not limited to, hair removal, hair growth and regrowth, and skin rejuvenation or resurfacing, acne removal or reduction, wrinkle reduction, pore reduction, ablation of cellulite and other dermal lipid depots, wart and fungus removal, thinning or removal of scars including hypertrophic scars and keloids, abnormal pigmentation (such as port wine stains), tattoo removal, and skin inconsistencies (e.g. in texture, color, tone, elasticity, hydration). Other therapeutic or preventative methods include but are not limited to treatment of hyperhidrosis, anhidrosis, Frey’s Syndrome (gustatory sweating), Horner’s Syndrome, and Ross Syndrome, actinici keratosis, keratosis follicularis, dermatisis, vitiligo, pityriasis, psoriasis, lichen planus, eczema, alopecia, psoriasis, malignant or non-malignant skin tumors.

[0019] Unless explained otherwise, all technical and scientific terms used herein have the same meaning as commonly understood to one of ordinary skill in the art to which this disclosure belongs. Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present disclosure, suitable methods and materials are described herein. The materials, methods, and examples are illustrative only and not intended to be limiting. Other features of the disclosure are apparent from the following detailed description and the claims.

[0020] “Administer” and “administration” as used herein, include providing or causing the provision of a material to a subject, such as by a topical, subdermal, subcutaneous, intradermal, enteral, parenteral, rectal, nasal, intravenous, intramuscularly, intraperitoneal, or other route.

[0021] A “carrier suitable for administration” to a subject is any material that is physiologically compatible with a topical or route of administration to a desired vertebrate subject. Carriers can include solid-based, dry materials for formulation; or the carrier can include liquid or gel-based materials for formulations into liquid or gel forms. The specific type of carrier, as well as the final formulation depends, in part, upon the selected route(s) of administration and the type of product.

[0022] A “comparable amount” is an amount that is measurably similar to a given reference or standard.

[0023] The “components” of a formulation include any products or compounds associated with or contained within it.

[0024] An “effective dose”, “effective amount” or “therapeutic amount” is an amount sufficient to elicit the desired pharmacological, cosmetic or therapeutic effects, thus resulting in effective prevention or treatment of a disease or disorder, or providing a benefit in a vertebrate subject.

[0025] A “therapeutic effect” or “therapeutically desirable effect” refers to a change in a domain or region being treated such that it exhibits signs of being effected in the manner desired, e.g., cancer treatment causes the destruction of tumor cells or halts the growth of tumor cells, acne treatment causes a decrease in the number and/or severity of blemishes, hair removal treatment leads to evident hair loss, or wrinkle reduction treatment causes wrinkles to disappear.

[0026] An “isolated” biological component (such as a nucleic acid molecule, protein, or cell) has been substantially separated or purified away from other biological components in which the component was produced, including any other proteins, lipids, carbohydrates, and other components.

[0027] A “nanoparticle”, as used herein, refers generally to a particle having at least one of its dimensions from about 0.1 nm to about 9000 nm.

[0028] A “subject” or “patient” as used herein is any vertebrate species.

[0029] As used herein, a “substantially pure” or “substantially isolated” compound is substantially free of one or more other compounds.

[0030] A “target tissue” includes a region of an organism to which a physical or chemical force or change is desired. As described herein, exemplary target tissues for acne treatment include a sebaceous gland, while exemplary target
EP 3 210 591 B1

tissues for hair removal include a pilosebaceous unit, a hair infundibulum, a hair follicle, or a non-follicular epidermis. A "region" of a target tissue includes one or more components of the tissue. Exemplary target tissue regions include the stem cell niche, bulge, sebaceous gland, dermal papilla, cortex, cuticle, inner root sheath, outer root sheath, medulla, Huxley layer, Henle layer or pylori muscle. A "domain" of a target tissue region includes basement membrane, extracellular matrix, cell-surface proteins, unbound proteins/analytes, glycomatrices, glycoproteins, or lipid bilayer.

[0031] A compound that is "substantially free" of some additional contents is largely or wholly without said contents.

[0032] A "plasmonic nanoparticle" is a nanometer-sized metallic structure within which localized surface plasmons are excited by light. These surface plasmons are surface electromagnetic waves that propagate in a direction parallel to the metal/dielectric interface (e.g., metal/air or metal/water).

[0033] A "light-absorbing nanomaterial" includes a nanomaterial capable of demonstrating a quantum size effect.

[0034] As described herein, provided are compositions that contain plasmonic nanoparticles to induce selective thermomodulation in a target tissue.

Plasmonic nanoparticles.

[0035] Such compositions contain from about $10^3$ to about $10^{16}$ nanoparticles, such as $10^3$, $10^4$, $10^5$, $10^6$, $10^9$, $10^{10}$, $10^{11}$, $10^{12}$, $10^{13}$, $10^{14}$, $10^{15}$, $10^{16}$ particles. Preferably, the compositions contain about $10^7$ to $10^{13}$ particles so that the amount of particles localized to an effective 1 ml treatment volumes is from $10^9$ to $10^{11}$. In certain embodiments wherein increased concentration of nanoparticles to a target region is desired, compositions contain particle concentrations with optical densities (O.D.) of $10^{-5}$ to 1000 O.D., or optical densities greater than 1,000 O.D. In some embodiments these correspond to concentrations of about 1-10% w/w or more of nanoparticles.

[0036] Nanoparticles may be homogenous or heterogeneous in size and other characteristics. The size of the nanoparticle is generally about 0.1 nm to about 5,000 nm in at least one dimension. Some variation in the size of a population of nanoparticles is to be expected. For example, the variation might be less than 0.01%, 0.1%, 0.5%, 1%, 5%, 10%, 15%, 25%, 50%, 75%, 100%, 200% or greater than 200%. In certain embodiments where optimal plasmonic resonance is desired, a particle size in the range of from about 10 nm to about 100 nm is provided. Alternatively, in embodiments where enhanced penetration of the nanoparticles into a target tissue region such as a hair follicle is desired, a particle size in the range of from about 100 nm to about 1000 nm is provided. Modulation of particle size present in the composition is also a useful means of concentrating the composition in a target domain. Further, as described herein, nanoparticles having a size range of from about 10 nm to about 100 nm can be used as component of a larger molecular structure, generally in the range of from about 100 nm to about 1000 nm. For example, the plasmonic nanoparticle can be surface coated to increase its size, embedded into an acceptable carrier, or it can be cross-linked or aggregated to other nanoparticles, or to other materials, that generate a larger particle. In certain embodiments where at least one dimension of at least one nanoparticle within a solution of plasmonic nanoparticles is below 50-100 nm, the nanoparticle surface can be coated with a matrix (e.g. silica) of 10-100 nm thickness or more in order to increase that dimension or particle to 50-100 nm or more. This increased dimension size can increase the delivery of all nanoparticles to a target region (e.g., hair follicle) and limit delivery to non-target region (e.g. dermis).

[0037] Important considerations when generating nanoparticles include: 1) the zeta potential (positive, negative, or neutral) and charge density of the particles and resulting compositions; 2) the hydrophilicity/hydrophobicity of the particles and resulting compositions; 3) the presence of an adsorption layer (e.g., a particle slippage plane); and 4) target cell adhesion properties. Nanoparticle surfaces can be functionalized with thiolated moieties having negative, positive, or neutral charges (e.g. carboxylic acid, amine, hydroxyl) at various ratios. Moreover, anion-mediated surface coating (e.g. acrylate, citrate, and others), surfacant coating (e.g., sodium dodecyl sulfate, sodium laurate 2-sulfate, ammonium lauryl sulfate, sodium octech-1/deceth-1 sulfate, lecithin and other surfactants including cetyl trimethylammonium bromide (CTAB), lipids, peptides), or protein/peptide coatings (e.g. albumin, ovalbumin, egg protein, milk protein, other food, plant, animal, bacteria, yeast, or recombinantly-derived protein) can be employed. Blockcopolymers are also useful. Further, one will appreciate the utility of any other compound or material that adheres to the surface of light-absorbing particles to promote or deter specific molecular interactions and improve particle entry into pores or follicles. In some embodiments, the particle surface is unmodified. Modulation of hydrophilicity versus hydrophobicity is performed by modifying nanoparticle surfaces with chemistries known in the art, including silanes, isothiocyanates, short polymers (e.g., PEG), or functionalized hydrocarbons. Polymer chains (e.g., biopolymers such as proteins, polysaccharides, lipids, and hybrids thereof; synthetic polymers such as polyethylene glycol, PLGA, and others; and biopolymer-synthetic hybrids) of different lengths and packing density are useful to vary the adsorption layer/slipage plane of particles.

[0038] Optical absorption. Preferred nanoparticles have optical absorption qualities of about 10 nm to about 10,000 nm, e.g., 100-500 nm. In specific embodiments, the nanoparticles have optical absorption useful to excitation by standard laser devices or other light sources. For example, nanoparticles absorb at wavelengths of about 755 nm (alexandrite lasers), in the range of about 800-810 nm (diode lasers), or about 1064 nm (Nd: YAG lasers). Similarly, the nanoparticles absorb intense pulsed light (IPL), e.g., at a range of about 500 nm to about 1200 nm.
Assembly. The nanoparticles provided herein can generally contain a collection of unassembled nanoparticles. By "unassembled" nanoparticles it is meant that nanoparticles in such a collection are not bound to each other through a physical force or chemical bond either directly (particle-particle) or indirectly through some intermediary (e.g. particle-cell-particle, particle-protein-particle, particle-analyte-particle). In other embodiments, the nanoparticle compositions are assembled into ordered arrays. In particular, such ordered arrays can include any three dimensional array. In some embodiments, only a portion of the nanoparticles are assembled, e.g., 5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 99% or greater than 99% of the nanoparticles are assembled in an ordered array. The nanoparticles are assembled by a van der Walls attraction, a London force, a hydrogen bond, a dipole-dipole interaction, or a covalent bond, or a combination thereof.

"Ordered array" "Ordered arrays" can take the form of a macrostructure from individual parts that may be patterned or unpatterned in the form of spheres, colloids, beads, ovals, squares, rectangles, fibers, wires, rods, shells, thin films, or planar surface. In contrast, a "disordered array" lacks substantial macrostructure.

Geometrically tuned nanostructures. The nanoparticles provided herein are formable in all shapes currently known or to be created that absorb light and generate a plasmon resonance at a peak-wavelength or composition of wavelengths from 200 nm to 10,000 nm. In non-limiting examples, the nanoparticles are shaped as spheres, ovals, cylinders, squares, rectangles, rods, stars, tubes, pyramids, stars, prisms, triangles, branches, plates or comprised of a planar surface. In non-limiting examples, the plasmonic particles comprise nanoshells, hollow nanoshells nanorods, nanorice, nanorods, nanowires, nanopyramids, nanoprisms, nanoparticles or a combination thereof. Plasmonic particles present in the composition comprise a substantial amount of geometrically-tuned nanostructures defined as 5, 10, 15, 25, 50, 75, 80, 85, 90, 95, 98, 99, 99.9 or greater than 99.9% of particles.

Composition. The nanoparticle is a metal (e.g., gold, silver), metallic composite (e.g., silver and silica, gold and silica), metal oxide (e.g. iron oxide, titanium oxide), metallic salt (e.g., potassium oxalate, strontium chloride), intermetallic (e.g., titanium aluminide, alnico), electric conductor (e.g., copper, aluminum), electric superconductor (e.g., yttrium barium copper oxide, bismuth strontium calcium copper oxide), electric semiconductor (e.g., silicon, germanium), dielectric (e.g., silica, plastic), or quantum dot (e.g., zinc sulfide, cadmium selenium). In non-limiting examples, the materials are gold, silver, nickel, platinum, palladium, silicon, gallium. Alternatively, the nanoparticle contains a composite including a metal and a dielectric, a metal and a semiconductor, or a metal, semiconductor and dielectric.

Coating. Preferentially, the composition contains coated nanoparticles.

Topical and Dermatological Applications. Target tissues for topical and dermatological applications include the surface of the skin, the epidermis and the dermis. Diseases or conditions suitable for treatment with topical and dermatological applications include acne, warts, fungal infections, psoriasis, scar removal, hair removal, hair growth, reduction of hypertrophic scars or keloids, skin inconsistencies (e.g. texture, color, tone, elasticity, hydration), and malignant or non-malignant skin tumors.

As used herein, the term “acne” includes acne vulgaris as well as other forms of acne and related cutaneous conditions, including acne aestivalis, acne conglobata, acne cosmetic, acne fulminans, acne keloidalisnuchae, acne mechanica, acne miliarisnecrotica, acne necrotica, chloracne, drug-induced acne, excoriated acne, halogen acne, lupus miliaris disseminates faciei, pomade acne, tar acne, and tropical acne.

Subdermal Applications. Target tissues for subdermal applications include the adipose tissue and connective tissue below the integumentary system. Diseases or conditions suitable for treatment with subdermal applications include wrinkles and tattoos. Other applications include skin rejuvenation and/or resurfacing, the removal or reduction of stretch marks and fat ablation.

Often, a specific region of the target tissue is a hair follicle, a sebaceous gland, a merocrine sweat gland, an apocrine sweat gland, or an arrector pili muscle, within which a specific domain is targeted. For example, the bulge region of the hair follicle is targeted. Because in one embodiment the nanoparticles are useful to thermally ablate hair follicle stem cells for hair removal, regions containing hair follicle stem cells are of particular interest for targeting. Thus, the target tissue region may include a stem cell niche, bulge, sebaceous gland, dermal papilla, cortex, cuticle, inner root sheath, outer root sheath, medulla, Huxley layer, Henle layer or pylori muscle. Each of these regions may contain cells, stem cells, basement membrane, extracellular matrix, growth factors, analytes, or other biologic components that mediate hair follicle rejuvenation. Disruption or destruction of these components would have a therapeutic effect, e.g. slow or stop the processes that mediate hair regrowth, prevent the secretion of sebum from the sebaceous gland, damage or deter tumor cells, reduce the appearance of wrinkles. Structures can also be targeted that are in close proximity to a desired target for ablation, especially when capable of conducting heat effectively.

Localization Domains. Provided are compositions containing nanoparticles that preferentially localize to a domain of a target tissue region of a mammalian subject to whom the composition is administered.

Targeting moieties. The nanoparticles can be engineered to selectively bind to a domain of the target tissue. For example, the nanoparticles are operably linked to the domain via a biologic moiety, in order to effectively target the nanoparticles to the target tissue domain. Preferably, the moiety contains a component of a stem cell, a progenitor cell, an extracellular matrix component, a basement membrane component, a hair shaft component, a follicular epithelial component, or a non-folicular epidermal component. Biological moieties include proteins such as cell surface receptors, glycoproteins or extracellular matrix proteins, as well as carbohydrates, analytes, or nucleic acids (DNA, RNA) as well as membrane components (lipid bilayer components, microsomes).

Delocalization Domains. Nanoparticles present in the composition preferentially delocalize away from a domain of a target tissue region. Delocalization domains include specific regions of a tissue into which nanoparticles do not substantially aggregate, or alternatively, are removed from the domain more effectively. In preferred embodiments, the delocalization domain is a non-folicular epidermis, dermis, a component of a hair follicle (e.g., a hair stem cell, a stem cell niche, a bulge, a sebaceous gland, a dermal papilla, a cortex, a cuticle, an inner root sheath, an outer root sheath, a medulla, a Huxley layer, a Henle layer, a pylori muscle), a hair follicle infundibulum, a sebaceous gland, a component of a sebaceous gland, a sebocyte, a component of a sebocyte, or sebum.

Energy sources. Provided herein are nonlinear excitation surface plasmon resonance sources, which include various light sources or optical sources. Exemplary light sources include a laser (ion laser, semiconductor laser, Q-switched laser, free-running laser, or fiber laser), light emitting diode, lamp, the sun, a fluorescent light source or an...
electroluminescent light source. Typically, the energy source is capable of emitting radiation at a wavelength from about 100, 200, 300, 400, 500, 1000, 2000, 5000 nm to about 10,000 nm or more. The nonlinear excitation surface plasmon resonance source is capable of emitting electromagnetic radiation, ultrasound, thermal energy, electrical energy, magnetic energy, or electrostatic energy. For example, the energy is radiation at an intensity from about 0.00005 mW/cm² to about 1000 TW/cm². The optimum intensity is chosen to induce high thermal gradients from plasmonic nanoparticles in regions from about 10 microns to hundreds of microns in the surrounding tissue, but has minimal residual effect on heating tissue in which particles do not reside within a radius of about 100 microns or more from the nanoparticle. In certain embodiments, a differential heat gradient between the target tissue region and other tissue regions (e.g., the skin) is greater than 2-fold, 3-fold, 5-fold, 10-fold, 15-fold, 20-fold, 50-fold, 100-fold, or greater than 100 fold.

The energy can be tuned by monitoring thermal heat gradients on the surface of the skin with a thermal/infrared camera. As demonstrated herein, the methods and systems of the present disclosure provide superior efficacy when a surface plasmon is generated on the nanoparticles by the action of the radiation. Typically, the plasmon is generated in a one-photon mode or, alternatively, a two-photon mode, a multi-photon mode, a step-wise mode, or an up-conversion mode.

Delivery of radiation. Physical means of delivery of the energy from the nonlinear excitation surface plasmon resonance source to the target tissue region include a fiber, waveguide, a contact tip or a combination thereof.

Optical sources include a CW optical source or a pulsed optical source, which may be a single wavelength polarized (or, alternatively, unpolarized) optical source capable of emitting radiation at a frequency from about 200 nm to about 10,000 nm. Alternatively, the optical source is a single wavelength polarized (or, alternatively, unpolarized) optical source capable of emitting radiation at a wavelength from about 200 nm to about 10,000 nm. The pulsed optical source is generally capable of emitting pulsed radiation at a frequency from about 1 Hz to about 1 THz. The pulsed optical source is capable of a pulse less than a millisecond, microsecond, nanosecond, picosecond, or femtosecond in duration. The optical source may be coupled to a skin surface cooling device to reduce heating of particles or structures on the skin surface and focus heating to components within follicles or tissue structures at deeper layers.

Nanoparticle-containing compositions. In order to provide optimal dermal penetration into the target tissue, the plasmonic nanoparticles in certain embodiments are formulated in various compositions. Preferentially, the nanoparticles are formulated in compositions containing 1-10% v/v surfactants (e.g. sodium dodecyl sulfate, sodium laureth 2-sulfate, ammonium lauryl sulfate, sodium octech-1/deceth-1 sulfate). Surfactants disrupt and emulsify sebum or other hydrophobic fluids to enable improved targeting of hydrophilic nanoparticles to the hair follicle, infundibulum, sebaceous gland, or other regions of the skin. Surfactants also lower the free energy necessary to deliver hydrophilic nanoparticles into small hydrophobic crevices such as the space between the hair shaft and follicle or into the sebaceous gland. Nanoparticle-containing compositions may also include emulsions at various concentrations (1-20% w/v) in aqueous solutions, silicone/oil solvents, propylene glycol or creams (e.g. comprising alcohols, oils, paraffins, colloidal silica). In other embodiments, the formulation contains a degradable or non-degradable polymer, e.g., synthetic polylactide/co-glycolide co-polymer, porous laurylactame/caprolactame nylon co-polymer, hydroxyethyl cellulose, polyelectrolyte monolayers, or alternatively, in natural hydrogels such as hyaluronic acid, gelatin and others. In further embodiments, a hydrogel PLGA, PEG-acrylate is included in the formulation. Other formulations include components of surfactants, a lipid bilayer, a liposome, or a microscope. A nanoparticle may comprise a larger micron-sized particle.

Effective doses. As described herein, an effective dose of the nanoparticle-containing compositions includes an amount of particles required, in some aspects, to generate an effective heat gradient in a target tissue region, such that a portion of the target tissue region is acted upon by thermal energy from excited nanoparticles. A "minimal effective dose" is the smallest number or lowest concentration of nanoparticles in a composition that are effective to achieve the desired biological, physical and/or therapeutic effect(s). Preferentially, the plasmonic nanoparticles have an optical density of 10 O.D.-1,000 O.D. at one or a plurality of peak resonance wavelengths.

Cosmetically acceptable carriers. Provided are cosmetic or pharmaceutical compositions with a plurality of plasmonic nanoparticles and a cosmetically or pharmaceutically acceptable carrier. Generally, the carrier and components must be suitable for topical administration to the skin of a mammalian subject, such that the plasmonic nanoparticles are present in an effective amount for selective thermomodulation of a component of the skin. Preferentially, the nanoparticles are formulated with a carrier containing 1-10% v/v surfactants (e.g. sodium dodecyl sulfate, sodium laureth 2-sulfate, ammonium lauryl sulfate, sodium octech-1/deceth-1 sulfate) to enable disruption of the epidermal skin barrier, emulsify sebum, improve mixing of hydrophilic nanoparticles with hydrophobic solutions, and reduce entropic barriers to delivering hydrophilic particles to hydrophobic regions of the skin (e.g. between the hair shaft and surrounding sheath or follicle). In some embodiments, the carrier contains a polar or non-polar solvent. For example, suitable solvents include alcohols (e.g., n-Butanol, isopropanol, n-Propanol, Ethanol, Methanol), hydrocarbons (e.g., pentane, cyclopentane, hexane, cyclohexane, benzene, toluene, 1,4-Dioxane), chloroform, Diethyl-ether, water, water with propylene glycol, acids (e.g., acetic acid, formic acid), bases, acetone, isocetanes, dimethyl sulfoxide, dimethylformamide, acetoneitrile, tetrahydrofuran, dichloromethane, ethylacetate, tetramethylammonium hydroxide, isopropanol, and others. In other em-
bodiments, a stabilizing agent such as antioxidants, preventing unwanted oxidation of materials, sequestrants, forming chelate complexes and inactivating traces of metal ions that would otherwise act as catalysts, emulsifiers, ionic or non-ionic surfactants, cholesterol or phospholipids, for stabilization of emulsions (e.g. egg yolk lecithin, Sodium stearoyl lactylate, sodium bis(2-ethylhexyl-sulfosuccinate (AOT)), ultraviolet stabilizers, protecting materials, especially plastics, from harmful effects of ultraviolet radiation is provided. In further embodiments, a composition with a cosmetically acceptable carrier is generated such that the nanoparticles are substantially in a suspension.

[0060] Other components are also optionally included, including an emulsion, polymer, hydrogel, matrix, lipid bilayer, liposome, or microsome. Additionally, inclusion of a detectable colorant (e.g., a pigment), a fragrance, a moisturizer, and/or a skin protectant is optional. In some examples, the formulation has a viscosity of above, below or within 0.1-1000 as measured in millipascal-seconds (mPa•s).

[0061] Nanoparticle quantities per milliliter in a composition are subject to modification for specific binding and can range from 10^9 to 10^18 particles but generally about 10^11 to 10^13 nanoparticles per milliliter. In certain embodiments wherein increased concentration of nanoparticles to a target region is desired, compositions contain particle concentrations with optical densities of 10 O.D.-1000 O.D., or optical densities greater than 1,000 O.D. In some embodiments these correspond to concentrations of about 0.1-10% w/w or more of nanoparticles.

[0062] Prior to application of nanoparticle formulations, skin and hair follicles can be pre-treated to increase the delivery of nanoparticles to a target region. In some embodiments, hair shafts are cut or removed via shaving, waxing, cyanoacrylate surface peels, calcium thioglycolate treatment, or other techniques to remove the hair shaft and/or hair follicle plugs and create a void wherein nanoparticles can accumulate. Orifices of active or inactive follicles can be blocked by plugs formed of comeocytes and/or other material (e.g. cell debris, soot, hydrocarbons, cosmetics). In some embodiments pre-treatment with surface exfoliation including mechanical exfoliation (e.g., salt glow or microdermabrasion) and chemical exfoliation (e.g., enzymes, alphahydroxy acids, or betahydroxy acids) removes plugs from the orifice of follicles to increase the targeting of nanoparticle formulations to target regions within the hair follicle.

[0063] In some embodiments, the nanoparticle formulations are formulated for application by a sponge applicator, cloth applicator, direct contact via a hand or gloved hand, spray, aerosol, vacuum suction, high pressure air flow, or high pressure liquid flow, roller, brush, planar surface, semi-planar surface, wax, ultrasound and other sonic forces, mechanical vibrations, hair shaft manipulation (including pulling, massaging), physical force, thermal manipulation, and other treatments. In some embodiments, nanoparticle formulation treatments are performed alone, in combination, sequentially or repeated 1-24 times. In other embodiments the plasmonic nanoparticles are capable of selectively localizing to a first component of the skin, where physical massage or pressure, ultrasound, or heat increase the selective localization of the nanoparticles to this first component. Additionally, the nanoparticles are selectively removable from components of the skin other than the first component, such removal accomplished with acetone, alcohol, water, air, peeling of the skin, chemical peeling, waxing, or reduction of the plasmonic compound. Further, in some embodiments the nanoparticles have a coat layer to increase solubility of the nanoparticles in the carrier and/or reduce "stickiness" and accumulation in non-target areas. The subject matter described herein also provides embodiments in which at least a portion of an exterior surface of the nanoparticle is modified, such as to include a layer of a polymer, polymeric monomer, non-polar monomer, biologic compound, a metal (e.g., metallic thin film, metallic composite, metal oxide, or metallic salt), a dielectric, or a semiconductor. Alternatively, the exterior surface modification is polar, non-polar, charged, ionic, basic, acidic, reactive, hydrophobic, hydrophilic, agonistic, or antagonistic. In certain embodiments where at least one dimension of at least one nanoparticle within a solution of plasmonic nanoparticles is below 50-100 nm, the nanoparticle surface can be coated with a matrix (e.g. silica) of 10-100 nm thickness or more in order to increase that dimension or particle to 50-100 nm or more. This increased dimension size can increase the delivery of all nanoparticles to a target region (e.g., hair follicle) and limit delivery to non-target region (e.g., dermis).

Penetration means.

[0064] Preferably, the compositions of the instant disclosure are topically administered. Provided herein area means to redistribute plasmonic particles from the skin surface to a component of dermal tissue including a hair follicle, a component of a hair follicle, a follicle infundibulum, a sebaceous gland, or a component of a sebaceous gland using high frequency ultrasound, low frequency ultrasound, massage, iontophoresis, high pressure air flow, high pressure liquid flow, vacuum, pre-treatment with Fractionated Photothermolysis laser or derm-abrasion, or a combination thereof. For example, the compositions can be administered by use of a sponge applicator, cloth applicator, spray, aerosol, vacuum suction, high pressure air flow, high pressure liquid flow direct contact by hand ultrasound and other sonic forces, mechanical vibrations, hair shaft manipulation (including pulling, massaging), physical force, thermal manipulation, or other treatments. Nanoparticle formulation treatments are performed alone, in combination, sequentially or repeated 1-24 times.
Cosmetic and therapeutic uses of plasmonic nanoparticles.

[0065] In general terms, Applicant(s) have created systems and methods for the cosmetic and therapeutic treatment of dermatological conditions, diseases and disorders using nanoparticle-based treatments methods.

Acne treatment.

[0066] Acne is caused by a combination of diet, hormonal imbalance, bacterial infection (Propionibacterium acnes), genetic predisposition, and other factors. The nanoparticle-based methods and systems described herein for acne treatment are able to focally target causative regions of the dermis, the sebaceous gland and the hair follicle, and thus have advantages compared to the existing techniques known in the art, including chemical treatment (peroxides, hormones, antibiotics, retinoids, and anti-inflammatory compounds), dermabrasion, phototherapy (lasers, blue and red light treatment, or photodynamic treatment), or surgical procedures.

[0067] In particular, laser-based techniques are becoming an increasingly popular acne treatment, but a substantial limitation is the lack of selective absorptive properties among natural pigments (e.g. fat, sebum) for specific wavelengths of light such that selective heating of one cell, structure, or component of tissue, particularly in the sebaceous glands, infundibulum, and regions of the hair follicle, is not achieved without heating of adjacent off-target tissue. The nanoparticles described herein provide significantly higher photothermal conversion than natural pigments enabling laser energy to be focused to specific cells, structures, or components of tissue within the sebaceous gland, infundibulum, or regions of the hair follicle for selective photothermal damage.

[0068] Using the materials and techniques described herein may provide acne treatments of greater duration than existing methodologies. In certain embodiments, tuned selective ablation of the sebaceous gland or infundibulum is achieved as described herein. In particular, plasmonic nanoparticles are specifically localized to regions of hair follicles in or proximate to the sebaceous gland or infundibulum.

[0069] Plasmonic nanoparticles exhibit strong absorption at wavelengths emitted by standard laser hair removal devices (e.g., 755 nm, 810 nm, 1064 nm) relative to surrounding epidermal tissue. Thus, irradiation of targeted plasmonic nanoparticles with laser light induces heat radiation from the particles to the adjacent sebum, sebaceous gland, infundibulum, and other acne causing agents.

Hair removal.

[0070] The nanoparticle-based methods and systems described herein for skin treatment have advantages compared to the existing techniques known in the art, including laser-based techniques, chemical techniques, electrolysis, electromagnetic wave techniques, and mechanical techniques (e.g., waxing, tweezers). Such techniques fail to adequately provide permanent hair removal across a breadth of subjects. In particular, subjects having light to medium-pigmented hair are not adequately served by these techniques, which suffer from side-effects including pain and the lack of beneficial cosmetic affects including hair removal. Laser-based techniques are popular in a variety of applications, but a substantial limitation is the lack of selective absorptive properties among natural pigments (e.g. melanin) for specific wavelengths of light such that selective heating of a cell, structure, or component of tissue is achieved without heating of adjacent off-target tissues. The nanoparticles described herein provide significantly higher photothermal conversion than natural pigments enabling laser energy to be focused to specific cells, structures, or components of tissue for selective photothermal damage.

[0071] More permanent reduction or removal of all hair types is provided herein, relative to hair removal treatments known in the art. In certain embodiments, tuned selective ablation of the hair shaft and destruction of stem cells in the bulge region is provided, as described herein. In particular, plasmonic nanoparticles are specifically localized to regions of hair follicles in or proximate to the bulge region, a stem cell-rich domain of the hair follicle. Moreover, the plasmonic nanoparticles are localized in close approximation of 50-75% of the hair shaft structure.

[0072] Plasmonic nanoparticles exhibit strong absorption at wavelengths emitted by standard laser hair removal devices (e.g., 755 nm, 810 nm, 1064 nm) relative to surrounding epidermal tissue. Thus, irradiation of targeted plasmonic nanoparticles with laser light induces heat radiation from the particles to the adjacent stem cells (or in some cases, the architecture of the hair shaft itself), resulting in cell death and a disruption of the normal regenerative pathway.

Non-malignant and malignant skin tumors.

[0073] Laser therapies for the prevention and treatment of non-malignant, malignant, melanoma and non-melanoma skin cancers have been focused largely on photodynamic therapy approaches, whereby photosensitive porphyrins are applied to skin and used to localize laser light, produce reactive oxygen species and destroy cancer cells via toxic radicals. For example, 5-ALA combined with laser treatment has been FDA-approved for the treatment of non-melanoma
skin cancer actinic keratoses, and it is used off-label for the treatment of widely disseminated, surgically untreated, or recurrent basal cell carcinomas (BCC). However, this procedure causes patients to experience photosensitivity, burning, peeling, scarring, hypo- and hyper-pigmentation and other side effects due to non-specific transdermal uptake of porphyrin molecules. The nanoparticles described herein provide significantly higher photothermal conversion than natural pigments and dyes, enabling laser energy to be focused to specific cells, structures, or components of tissue for selective thermomodulation.

Using the materials and techniques described herein may provide cancer treatments of greater degree and duration than existing methodologies. In certain embodiments, tuned selective ablation of specific target cells as described herein. In particular, plasmonic nanoparticles are specifically localized to regions of hair follicles where follicular bulge stem cells arise to form nodular basal cell carcinomas and other carcinomas. Plasmonic nanoparticles may also be delivered to other target cells that cause tumors, for example, the interfollicular epithelium, which include the cell of origin for superficial basal cell carcinomas.

Plasmonic nanoparticles exhibit strong absorption at wavelengths emitted by standard laser hair removal devices (e.g., 755 nm, 810 nm, 1064 nm) relative to surrounding epidermal tissue. Thus, irradiation of targeted plasmonic nanoparticles with laser light induces heat radiation from the particles to the adjacent keratinocyte, melanocyte, follicular bulge stem cell, cancer cell, or cancer cell precursor, resulting in cell death or inhibited cell growth for cancer prevention and treatment.

Subdermal Applications. Target tissues for subdermal applications include the adipose tissue and connective tissue below the integumentary system. Diseases or conditions suitable for treatment with subdermatological applications include wrinkles and tattoos. Other applications include skin rejuvenation and/or resurfacing, the removal or reduction of stretch marks and fat ablation.

Vascular Applications. Target tissues for vascular applications include arteries, arterioles, capillaries, veins, and venules. Diseases or conditions suitable for treatment with vascular applications include spider veins, leaky valves, and vascular stenosis. In particular, vein abnormalities account for a substantial proportion of cosmetic diseases or conditions affecting the vasculature. Individuals with vein abnormalities such as spider veins or faulty venous valves suffer from pain, itchiness, or undesirable aesthetics.

Additionally, there are several indication for which ablation of other vessels including arteries, arterioles, or capillaries could provide therapeutic or cosmetic benefit including: 1) ablation of vasculature supplying fat pads and/or fat cells, 2) ablation of vasculature supporting tumors/cancer cells, 3) ablation of vascular birth marks (port-wine stains, hemangiomas, macular stains), and 4) any other indication whereby ablation of vessels mediates the destruction of tissue and apoptosis or necrosis of cells supported by those vessels with therapeutic or cosmetic benefit. Provided herein are methods for using the compositions described herein for the selective destruction of component(s) of veins from plasmonic nanoparticles focially or diffusely distributed in the blood. Plasmonic nanoparticles are combined with a pharmaceutically acceptable carrier as described above and are introduced into the body via intravenous injection. Nanoparticles diffuse into the blood and, in some embodiments, localize to specific vascular tissues. Subsequently, the nanoparticles are activated with laser or light-based systems as known in the art for treating skin conditions such as hair removal or spider vein ablation. Alternatively, image or non-image guided fiber optic waveguide-based laser or light systems may be used to ablate vessel or blood components in larger veins. In one embodiment, a device with dual functions for both injecting nanoparticles and administering light through on optical waveguide may be used. Activated nanoparticles heat blood and adjacent tissue (vessels, vessel walls, endothelial cells, components on or in endothelial cells, components comprising endothelial basement membrane, supporting mesenchymal tissues, cells, or cell components around the vessel, blood cells, blood cell components, other blood components) to ablative temperatures (38-50 degrees C or higher).

Provided herein is a composition comprising a pharmaceutically acceptable carrier and a plurality of plasmonic nanoparticles in an amount effective to induce thermomodulation of a vascular or intravascular target tissue region with which the composition is intravenously contacted. Furthermore, the composition of plasmonic nanoparticle may comprise a microvascular targeting means selected from the group consisting of anti-microvascular endothelial cell antibodies and ligands for microvascular endothelial cell surface receptors. Also provided is a method for performing thermoablation of a target vascular tissue in a mammalian subject, comprising the steps of contacting a region of the target vascular tissue with a composition comprising a plurality of plasmonic nanoparticles and a pharmaceutically acceptable carrier under conditions such that an effective amount of the plasmonic nanoparticles localize to a domain of the target vascular region; and exposing the target tissue region to energy delivered from a nonlinear excitation surface plasmon resonance source in an amount effective to induce thermoablation of the domain of the target vascular region.

Oral and nasal Applications. Target tissues for oral applications include the mouth, nose, pharynx, larynx, and trachea. Diseases or conditions suitable for treatment with vascular applications include oral cancer, polyps, throat cancer, nasal cancer, and Mournier-Kuhn syndrome.

Endoscopic Applications. Target tissues for endoscopic applications include the stomach, small intestine, large intestine, rectum and anus. Diseases or conditions suitable for treatment with vascular applications include gastrointestinal...
Methods of thermomodulation. Provided are methods for performing thermomodulation of a target tissue region. A nanoparticle composition comprising a plurality of plasmonic nanoparticles under conditions such that an effective amount of the plasmonic nanoparticles localize to a domain of the target tissue region; and exposing the target tissue region to energy delivered from a nonlinear excitation surface plasmon resonance source in an amount effective to induce thermomodulation of the domain of the target tissue region.

Removal of non-specifically bound nanoparticles. Removing nanoparticles localized on the surface of the skin may be performed by contacting the skin with acetone, alcohol, water, air, a debriding agent, or wax. Alternatively, physical debridement may be performed. Alternatively, one can perform a reduction of the plasmonic compound.

Amount of energy provided. Skin is irradiated at a fluence of 1-60 Joules per cm² with laser wavelengths of about, e.g., 750 nm, 810 nm, 1064 nm, or other wavelengths, particularly in the range of infrared light. Various repetition rates are used from continuous to pulsed, e.g., at 1-10 Hz, 10-100 Hz, 100-1000 Hz. While some energy is reflected, it is an advantage of the subject matter described herein is that a substantial amount of energy is absorbed by particles, with a lesser amount absorbed by skin. Nanoparticles are delivered to the hair follicle, infundibulum, or sebaceous gland at concentration sufficient to absorb, e.g., 1.1-100x more energy than other components of the skin of similar volume. This is achieved in some embodiments by having a concentration of particles in the hair follicle with absorbance at the laser peak of 1.1-100x relative to other skin components of similar volume.

To enable tunable destruction of target skin structures (e.g., sebaceous glands, infundibulum, hair follicles), light-absorbing nanoparticles are utilized in conjunction with a laser or other excitation source of the appropriate wavelength. The light source may be applied continuously or in pulses with a single or multiple pulses of light. The intensity of heating and distance over which photothermal damage will occur are controlled by the intensity and duration of light exposure. In some embodiments, pulsed lasers are utilized in order to provide localized thermal destruction. In some such embodiments, pulses of varying durations are provided to localize thermal damage to within 0.05, 0.1, 0.5, 1, 2, 5, 10, 20, 30, 50, 75, 100, 200, 300, 500, 1000 microns of the particles. Pulses are at least femtoseconds, picoseconds, microseconds, or milliseconds in duration. In some embodiments, the peak temperature realized in tissue from nanoparticle heating is at least 5, 10, 15, 20, 25, 30, 40, 50, 60, 70, 80, 90, 100, 200, 300, or 500 degrees Celsius. In some embodiments that utilize pulsed heating, high peak temperatures are realized locally within the hair shaft without raising the macroscopic tissue temperature more than 0.1, 0.5, 1, 2, 5, 10, 20, 30, 50, 75, 100, 200, 300, or 500 degrees Celsius. In some embodiments short pulses (100 nanoseconds-1000 microseconds) are used to drive very high transient heat gradients in and around the target skin structure (e.g., sebaceous gland and/or hair follicle) from embedded particles to localize damage in close proximity to particle location. In other embodiments, longer pulse lengths (1-500 ms) are used to drive heat gradients further from the target structure to localize thermal energy to stem cells in the bulge region or other components greater than 100 μm away from the localized particles. Fluences of 1-30 Joules per cm² are generally sufficient to thermally ablate follicles that have high particle concentrations and thus higher absorbance than skin (e.g., 1.1-100 times per volume absorbance of skin). These fluences are often lower than what is currently employed (e.g., Diode: 25-40 J/cm², Alexandrite: 20 J/cm², Nd:YAG: 30-60 J/cm²) and lead to less damage to non-follicular regions, and potentially less pain.

Plasmon Resonance Systems. Provided are plasmon resonance systems containing a surface that includes a plurality of plasmonic nanoparticles, and a nonlinear excitation source. Preferably, the surface is a component of skin that is targeted for cosmetic or therapeutic treatment (e.g., bulge region for hair removal, infundibulum or sebaceous gland for acne prevention). Also provided as a component of the system is a means for delivering plasmonic nanoparticles to the skin surface, such as an applicator, a spray, an aerosol, vacuum suction, high pressure air flow, or high pressure liquid flow. Further provided are means of localizing plasmonic nanoparticles to a component of the skin (e.g., hair follicle, bulge region, sebaceous gland, infundibulum). Useful surface delivery means include a device that generates high frequency ultrasound, low frequency ultrasound, heat, massage, contact pressure, or a combination thereof.

Further provided are systems that contain a removal means for removing nanoparticles on a non-follicular portion of the skin. The removal means includes at least one of acetone, alcohol, water, air, chemical peeling, wax, or a compound that reduces the plasmonic compound.

In addition, the systems of the present disclosure provide nonlinear excitation source that generates a continuous wave optical source or a pulsed optical source. Alternatively, the nonlinear excitation source is capable of generating electromagnetic radiation, ultrasound, thermal energy, electrical energy, magnetic energy, or electrostatic energy. Provided are systems wherein the nonlinear excitation source is capable of irradiating the nanoparticles with an intensity from about 0.00005 mW/cm² to about 1000 TW/cm². Further, the nonlinear excitation source is capable of functioning in a one-photon mode, two-photon mode, multi-photon mode, step-wise mode, or up-conversion mode. A fiber, a waveguide, a contact tip, or a combination thereof may be used in the instant systems.

In some embodiments, the system contains a monitoring device such as a temperature sensor or a thermal...
energy source. In other embodiments, the systems also contain a controller means for modulating the nonlinear excitation source (e.g., a "feedback loop controller"). In a related embodiment, the system contains a means for detecting a temperature of the surface or a target tissue adjacent to the surface, wherein the controller means modulates the intensity of the nonlinear excitation source and/or the duration of the excitation. In such embodiments, the controller means preferably modulates the intensity of the nonlinear excitation source such that a first component of the hair follicle is selectively thermooxidized relative to a second component of the hair follicle. In further embodiments, a cooling device is directly contacted with the skin during irradiation to minimize the heating of nanoparticles or skin at the surface, while nanoparticles that have penetrate more deeply into the follicle, skin, or sebaceous gland heat to temperatures that selectively ablate the adjacent tissues.

[0090] Skin is an exemplary target tissue. The skin preferably contains a hair follicle and/or a sebaceous gland, where the nonlinear excitation source generates energy that results in heating the skin in an amount effective to induce thermo-oxidation of a hair follicle, an infundibulum, a sebaceous gland, or a component thereof, such as by heating sufficient to cause the temperature of the skin to exceed 37°C, such as 38°C, 39°C, 40°C, 41°C, 42°C, 43°C, 44°C, 45°C, 46°C, 47°C, 48°C, 49°C, to about 50°C or greater.

[0091] Methods of Formulation. Also provided are methods for formulating the nanoparticles of the present disclosure into a form suitable for use as described herein. In particular, the nanoparticle compositions are generated by:

a) forming a first mixture containing a plurality of nanoparticles and a first solvent;
b) exchanging the first solvent for a second solvent to form a second mixture; and
c) combining the second mixture and a cosmetically or pharmaceutically acceptable carrier; thereby forming a nanoparticle composition.

[0092] The exchanging step is optionally performed using liquid chromatography, a solvent exchange system, a centrifuge, precipitation, or dialysis. Preferably, the nanoparticles are surface modified through a controlled reduction step or an oxidation step. Such surface modification may involve a coating step, such as the adsorbance of a monomer, polymer, or biological entity to a surface of the nanoparticle. Typically, the coating step involves contacting the nanoparticles with an oxidative environment. Further, the coating step may include monomer polymerization to create polymer coat.

[0093] The methods described herein may also include the steps of dissolving the nanoparticles in a non-polar solvent and subsequently mixing the dissolved nanoparticles with a polar solvent so as to encapsulate the nanoparticles in an emulsion. Further, the addition of surfactants (e.g. sodium dodecyl sulfate, sodium laurate 2-sulfate, ammonium lauryl sulfate, sodium octech-1/deceth-1 sulfate) at concentrations of 0.1-10% may be used to disrupt the epidermal skin barrier, emulsify the sebum and enable improved mixing of hydrophilic nanoparticles in aqueous solutions. Further, a concentration of the nanoparticles such as centrifugation or lyophilization may be employed. Further, the nanoparticles may be pretreated with heat or radiation. Also provided is the optional step of conjugating a biological entity or plurality of biological entities to the nanoparticles. Such a conjugating step may involve a thiol, amine, or carboxyl linkage of the biological entities to the nanoparticles.

[0094] Diseases and disorders. The present disclosure can be used on human (or other animal) skin for the treatment of wrinkles and other changes related to photo-aging or chronologic aging. The present disclosure can be used on human skin for the treatment of diseases including skin diseases, for the reduction of acne and related disorders such as rosacea, folliculitis, pseudofolliculitis barbae or proliferative or papulosquamous disorders such as psoriasis, for the stimulation or reduction of hair growth, and for reduction of cellulite, warts, hypopigmentation such as post-wine stain (PWS; nevus flammeus), birthmarks, hyperhidrosis, varicose veins, pigment problems, tattoos, vitiligo, melasma, scars, stretch marks, fungal infections, bacterial infections, dermatological inflammatory disorders, musculoskeletal problems (for example, tendinitis or arthritis), to improve healing of surgical wounds, burn therapy to improve healing and/or reduce and minimize scarring, improving circulation within the skin, and the like.

[0095] The present disclosure can also be useful in improving wound healing, including but not limited to chronic skin ulcers, diabetic ulcers, thermal burn injuries, viral ulcers or disorders, periodontal disease and other dental disease. The present disclosure, in certain embodiments, is also useful in enhancing the effects of devices that create an injury or wound in the process of performing cosmetic surgery including non-ablative thermal wounding techniques for treating skin wrinkles, scars, stretch marks and other skin disorders. Under such circumstances, it may be preferable to use conventional non-ablative thermal treatments in combination with the methods of the present disclosure. The instant application, in certain embodiments, are used in conjunction with micro- or surface abrasion, dermabrasion, or enzymatic or chemical peeling of the skin or topical cosmeceutical applications, with or without nanoparticle application to enhance treatment, as the removal of the stratum corneum (and possibly additional epithelial layers) can prove beneficial for some treatment regimen. The methods of the present disclosure are particularly applicable to, but are not limited to, acne treatment, hair removal, hair growth/hair follicle stimulation, reduction/prevention of malignant and non-malignant skin tumors, and skin rejuvenation, as described herein.
The dermatologically therapeutic methods described herein may be formed using nanoparticle irradiation alone, nanoparticle irradiation in combination with nano- or microparticles, or nanoparticle irradiation with a composition comprising nano- or microparticles and one or more therapeutic agents. Such nanoparticle irradiation may be produced by any known nanoparticle generator, and is preferably a focused nanoparticle generator capable of generating and irradiating focused nanoparticle waves.

EXAMPLES

Example 1. Generation of plasmonic nanoparticles for thermomodulation.

Plasmonic nanoparticles, including nanorods, hollow nanoshells, silicon nanoshells, nanoplates, nanorice, nanowires, nanoprisms, nanoplates and other configurations described herein and known to those skilled in the art, are generated in size ranges from 1-1000 nm under conditions such that surface properties that facilitate deep follicular penetration. Surface properties can be varied on one or multiple (2, 3, or 4) different dimensions to increase nanoparticle concentration in a target tissue domain. Penetration into follicular openings of 10-200 um can be maximized using the nanoparticles described herein. Here, nanoparticles sized in the range of about 10 to about 100 nm are generated, and are preferably assembled or formulated into multiparticular structures having a size in the range of 100-300 nm. Alternatively, a coating (e.g., silica) is grown on uniparticular structures to increase the particle size to the range of 100-300 nm or more.

Surface-modified plasmonic nanoparticles. An exemplary preparation of surface-modified plasmonic nanoparticles is provided as follows. Plasmonic nanoparticles are synthesized with stable cetyltrimethylammonium bromide (CTAB) coating and concentrated from an optical density of 1.0D. to 100, 200, 300, 400, or 500 O.D. through one to three cycles of centrifugation at 16,000 rcf, with supernatant decanting. Alternatively, CTAB-coated nanoparticles are concentrated and resuspended in 250 Amol/L 5-kDa methyl-polyethylene glycol (PEG)-thiol to make PEG-coated nanoparticles. Verification that PEG polymer stocks are fully reduced is performed using spectrophotometry to measure the thiol activity of polymer-thiols with 5,5-dithiobis(2-nitrobenzoic acid) against a DTT gradient. The solution of methy-PEG-thiol and CTAB-coated nanoparticles is mixed at room temperature for 1 h then dialyzed against 5 kDa MWCO in 4 L distilled water for 24 h. Dialyzed samples are processed through 100-kDa filters to remove excess polymer. Quantification of the number of PEG polymers per particle is performed by surface-modifying nanoparticles with amino-PEG-thiol polymer and quantifying the number of amines with an SPDP assay. For test formulations, 100 O.D. solutions of CTAB-coated nanoparticles are made in distilled water, and 100 O.D. PEG-coated plasmonic nanoparticles are made in distilled water, ethanol, DMSO, or mineral oil. Plasmonic nanoparticles with silica shells are created by reacting nanoparticles with silicates such as tetra-ethyl-ortho-silicate (TEOS), sodium silicate, aminopropyletriethoxysilane (APTS), etc. to thicknesses of 5-50 nm or more. Control, vehicle-only formulations contain no nanoparticles.

Example 2. Formulation of thermoablative plasmonic nanoparticles for topical delivery.

Nanoparticles are generated as in Example 1 using an appropriate solvent (e.g., water, ethanol, dimethyl sulfoxide). The mixture comprising a plurality of nanoparticles in water is concentrated to about 100-500 O.O.D. and exchanged for a new solvent by liquid chromatography, a solvent exchange system, a centrifuge, precipitation, or dialysis. The solvent may include an alcohol (e.g., n-Butanol, isopropanol, n-Propanol, Ethanol, Methanol), a hydrocarbon (e.g., pentane, cyclopentane, hexane, cyclohexane, benzene, toluene, 1,4-Dioxane), chloroform, Diethyl-ether, water, an acid (e.g., acetic acid, formic acid), a base, acetone, dimethyl sulfoxide, dimethylformamide, acetonitrile, tetrahydrofuran, dichloromethane, or ethylacetate. The new solvent is combined with a cosmetically or pharmaceutically acceptable carrier, thereby forming a nanoparticle composition. Generally, the particles and carrier will form an emulsion.

Plasmonic nanoparticle formulations are provided that amplify or expedite the penetration of nanoparticles into hair follicles. In some embodiments, nano- and microemulsions facilitate partitioning within lipid-rich skin compartments.
such as the hair follicle. In some embodiments, nanoparticles are formulated in compositions containing 0.5-2% v/v surfactants to enable disruption of the epidermal skin barrier, emulsification of sebum, and improved mixing of hydrophilic nanoparticles in hydrophobic solutions or targeting to hydrophobic space in the skin (e.g. between the hair shaft and surrounding follicle). Formulations of nanoparticles are also provided at various concentrations (1-20% w/v) in aqueous solutions, silicone/oil solvents, propylene glycol or creams (e.g. containing alcohols, oils, paraffins, colloidal silicas). In some embodiments, light-absorbing nanoparticles are utilized in solutions having tailored pH, temperature, osmolyte concentration, viscosity, volatility, and other characteristics to improve light-absorbing nanoparticle entry into hair follicles.

[0102] Formulations are prepared to maximize nanoparticle stability (degree of aggregation in solution), nanoparticle concentration, and nanoparticle absorbance (degree of laser-induced heating at different concentrations).

[0103] When formulations of plasmonic nanoparticles are illuminated with a clinical laser with a wavelength coincident to the peak absorption wavelength of the particle, the formulation heats to thermoablativle temperatures more rapidly and to a greater degree than conventional clinical absorptive dyes. Figure 2 compares the temperature profile of plasmonic particles (1020 nm peak absorption wavelength) to conventional clinical dyes carbon lotion, meladine spray and indocyanine green after exposure to 1064 nm, 20 J/cm², 55 ms laser pulses. The temperature increase caused by pulsed 1064 nm laser light was more than 2.5 times greater for the plasmonic solution, compared to conventional clinical dyes used at the same dilution (1:1000 dilution from clinical concentration, where clinical concentrations are as follows: carbon 20-200 mg/ml, meladine 1 mg/ml, indocyanine green 5 mg/ml).

Example 3. Use of plasmonic nanoparticles for thermomodulation of hair.

[0104] Individuals having blonde, red, gray, or lightly-colored hair are not adequately treated with existing light-based hair removal techniques. Provided herein are methods for using the compositions described herein for the selective removal or reduction of untreated blonde, red, gray, or lightly-colored hair. Plasmonic nanoparticles generated and formulated as described above are introduced into a target tissue region, generally a skin region, and activated with laser-based hair removal systems as known in the art in order to achieve effective hair removal.

[0105] To achieve maximal penetration depth and concentration of plasmonic nanoparticles in the hair follicle and/or near components of the sebaceous gland including the sebaceous duct, the sebum, the epithelial linking of the sebaceous gland, and/or near the bulge region including the stem cells, stem cell niche, epithelial lining of the bulge region, and/or near the follicular bulb, an optimal particle size of 30-800 nm containing one or several plasmonic nanoparticles is constructed. Nanoparticles encapsulating plasmonic nanoparticles can be formulated from any number of polymers or matrices. In some embodiments, the formulation contains a degradable or non-degradable polymer, e.g., synthetic polylactide/co-glycolide co-polymer, porous lauryllactame/caprolactame nylon co-polymer, hydroxylcellulose, polyelectrolyte monolayers, or alternatively, in natural hydrogels such as hyaluronic acid, gelatin and others. In further embodiments, a hydrogel PLGA, PEG-acrylate is included in the formulation. Preferentially, a matrix component such as silica, polystyrene or polyelethylene glycol is provided in the formulation to improve particle stability and enable facile removal from the skin surface after application and follicle targeting. Other formulations include component of surfactants (e.g. sodium dodecyl sulfate, sodium laureth 2-sulfate, ammonium lauryl sulfate, sodium octeh-1/deceth-1 sulfate), a lipid bilayer, a liposome, or a microsome. Plasmonic nanoparticles including nanorods, nanoshells, nanospheres, nanoplates, or nanorice can be encapsulated within a the polymer or lipid-based nanoparticle or matrix or deposited on the particle surface. Alternatively, nanoparticles in the size range of 100-250 nm, 250-500 nm, 800 nm-1500 nm, or greater than 1500 nm can be used.

[0106] Pre-treatment of skin with mechanical or chemical exfoliation is used in some embodiments to remove hair-plugs and "open" the follicle for particle delivery. Additionally, hairs can be shaven or waxed to create a void in the hair follicle for particles to fill. The use of physical or thermal force amplifies or expedites the penetration of light absorbing nanoparticles and conjugates thereof into hair follicles, in part by causing dilation of the hair follicle prior to application of the nanoparticles. For example, ultrasound and other sonic forces, mechanical vibrations, hair shaft manipulation (including pulling), physical force, thermal manipulation, and other treatments are utilized to improve entry of light-absorbing nanoparticles into hair follicles. Nanoparticle formulation treatments are performed alone, in combination, sequentially or repeated 1-24 times.

[0107] An applicator is used to uniformly apply the composition of nanoparticles into follicles. The applicator can be a sponge, a cloth, direct contact from a finger, a tube, a syringe, a device that applies suction, an aerosol, a spray, or other means known in the art. In one example, a formulation of 1ml of plasmonic nanoparticles at a concentration of 100 O O.D. with peak resonance of 810 nm is applied to approximately 200cm² area of the skin of an adult human subject with a syringe. A cloth is used to evenly distribute solution across the skin area and into the hair follicles. Deep massage from a mechanical vibrator for 2 minutes with or without 1 MHz ultrasound for 5 minutes, is applied to drive particles deep into the follicle. Particles penetrate 50-75% down the full length of the hair shaft at concentrations sufficient to heat skin in a 100μm radius at incremental temperatures of 5-20-fold greater than is generated in similar volumes of adjacent skin when irradiated by a Diode (810 nm) laser. Acetone, ethanol, or a debriding agent can be used to remove
Hair follicle penetration of nanoparticles in hairless rodents, albino rodents and dark-haired rodents. Efficacy on live human skin is measured by measuring hair counts at various depths along the follicle, in quadruplicate 5-µm sections on a microtome in transverse directions. Slides with mounted paraffin sections are deparaffinized and stained with hematoxylin and eosin (H&E) or kept unstained for dark field microscopy. Alternatively, plasmonic nanoparticles are directly visualized by dark field microscopy after histological sectioning or follicular biopsy. To assess nanoparticle concentrations at various depths along the follicle, excised skin samples are separated by tape stripping or heat-based techniques, samples are dissolved for bulk analysis of metal concentration by ICP-MS (inductively coupled plasma-mass spectrometry). The macroscopic degree of heating is validated by infrared thermography of skin samples, and by assessment of skin sections subject to laser exposure for thermal damage markers. Finally, one can measure efficacy of photothermal destruction at the nanoparticle accumulation site by analyzing histological cellular lesions at the target site, including the follicular hair shaft, inner root sheath, outer root sheath, and bulge region containing the stem cell niche, which contains the stem cells that contribute to new hair growth. As the bulge region is generally localized about midway (~50% down the length of) the hair shaft, permanent hair removal is sufficiently achieved by accumulation of plasmonic nanoparticles to this depth. In some situations, nanoparticle delivery may also generate a heat gradient emitting further down the hair shaft. Animal studies are useful to demonstrate the efficacy of unpigmented hair removal by comparing heat profiles, thermal ablation of hair shaft, and thermal damage of bulge stem cells in treated hairless rodents, albino rodents and dark-haired rodents. Efficacy on live human skin is measured by measuring hair counts at 3 and 12 month follow ups. Biopsies are taken from select patients at 2, 4, and 6 week follow ups to verify that nanoparticles are cleared from the skin without embedding in the dermis.

Nanoparticle formulations are tested in ex vivo animal samples, ex vivo human skin samples, and in vivo human skin including the assessment of: 1) depth of nanoparticle penetration into hair follicles; 2) particle concentration achieved; 3) degree of heating achieved at delivered nanoparticle concentrations; and 4) efficacy of photothermal destruction including temporary and permanent hair removal. To assess nanoparticle penetration depths, plasmonic nanoparticles surface-functionalized with fluorescent molecules are visualized by fluorescence microscopy after histological sectioning or follicular biopsy (removal of hair shaft). Alternatively, plasmonic nanoparticles are directly visualized by dark field imaging after histological sectioning or follicular biopsy. To assess nanoparticle concentrations at various depths along the follicle, the excised skin samples are separated by tape stripping or heat-based techniques, samples are dissolved for bulk analysis of metal concentration by ICP-MS (inductively coupled plasma-mass spectrometry). The macroscopic degree of heating is validated by infrared thermography of skin samples, and by assessment of skin sections subject to laser exposure for thermal damage markers. Finally, one can measure efficacy of photothermal destruction at the nanoparticle accumulation site by analyzing histological cellular lesions at the target site, including the follicular hair shaft, inner root sheath, outer root sheath, and bulge region containing the stem cell niche, which contains the stem cells that contribute to new hair growth. As the bulge region is generally localized about midway (~50% down the length of) the hair shaft, permanent hair removal is sufficiently achieved by accumulation of plasmonic nanoparticles to this depth. In some situations, nanoparticle delivery may also generate a heat gradient emitting further down the hair shaft. Animal studies are useful to demonstrate the efficacy of unpigmented hair removal by comparing heat profiles, thermal ablation of hair shaft, and thermal damage of bulge stem cells in treated hairless rodents, albino rodents and dark-haired rodents. Efficacy on live human skin is measured by measuring hair counts at 3 and 12 month follow ups. Biopsies are taken from select patients at 2, 4, and 6 week follow ups to verify that nanoparticles are cleared from the skin without embedding in the dermis.

Hair follicle penetration of fluorescently-labeled nanoparticles determined using porcine skin explants and confocal imaging. A 25 mg/ml aqueous solution silicon dioxide-coated nanoparticles (200 nm diameter) was contacted with freshly thawed porcine skin, after which excess nanoparticle suspension was removed and manual massage was performed for three minutes. The explant was sectioned and subjected to confocal imaging. As shown in Figure 3A, explant sections were imaged at angles to the hair follicles in 60 µm planes; Plane 1 shows the follicle infundibulum, while Plane 2 shows the distal regions of the follicle. Figure 3B demonstrates representative confocal images showing that red nanoparticles (548 nm absorbance) are visible within both the superficial and deep follicles, but are not detectable in dermal layers beneath the follicles. Figure 3C shows high-magnification imaging of red nanoparticles localized to and retained within a deep follicle (~400 µm). Green color indicates tissue autofluorescence (488 nm).

Hair follicle penetration of plasmonic nanoparticles determined using porcine skin and dark field imaging. A 100 O.D. suspension of plasmonic nanoparticles (200 nm diameter) was contacted with freshly thawed porcine skin, after which excess nanoparticle suspension was removed and manual massage was performed for three minutes. The procedure was repeated for a total of 3 applications, and surface residue removed with several 3-5 applications of alternating water and ethanol. The skin sample was excised, fixed, sectioned along horizontal plane and subjected to dark field imaging. As shown in Figure 4A, skin samples were sectioned and imaged horizontal to the hair follicle at various depths. In skin section images, plasmonic nanoparticles were observed as bright blue color point sources at depths up to 1.2 mm deep in porcine follicle spaces (Figure 4B). Control samples with no plasmonic nanoparticles were clearly differentiated (Figure 4C). ICP-MS is also performed on skin sections to assess nanoparticle concentrations at various depths along the follicle.

Hair follicle penetration of plasmonic nanoparticles in hairless rodents, albino rodents and dark-haired rodents. White-haired Swiss Webster mice (n=3) at 8 weeks old are anesthetized with injectable ketamine/xylazine anesthetic solution and dorsal back skin and hair washed and dried. Prior to formulation administration, three 10 cm x 10 cm areas are demarcated by permanent marker on each mouse and subjected to hair removal by 1) electric razor, 2) Nair depilation reagent, or 3) warm wax/rosin mixture application and stripping. Each mouse is treated by pipette with up to 3 nanoparticle formulations, in quadruplicate 5-µl spot sizes per demarcated skin area (up to 12 spots per area or 36 spots per mouse). Precise spot locations are demarcated with pen prior to pipetting. Duplicate treatment spots on the dorsal left side are massaged into skin for 5 minutes, while duplicate treatment spots on the dorsal right side are applied without massage. Thirty minutes after application, mice are sacrificed by carbon dioxide asphyxiation and cervical dislocation, and skin is carefully excised and punched into sections along spot size demarcations. Skin biopsies are fixed in 10% paraformaldehyde, paraffin-embedded, and cut into 5-µm sections on a microtome in transverse directions. Slides with mounted paraffin sections are deparaffinized and stained with hematoxylin and eosin (H&E) or kept unstained for dark field microscopy. Using H&E staining, light microscopy and/or dark field microscopy, greater than 50 follicles per formulation are imaged, and scoring is performed for skin sections for visible macroscopic nanoparticle accumulation in the follicle, along the hair shaft, at the site of the putative bulge stem cell niche, and at the depth of the follicle bulb. On serial histological sections, a silver enhancement staining kit based on sodium thiosulfate may be used to enlarge the plasmonic penetration.
Assessment of photothermal destruction at the nanoparticle accumulation site. Treated areas of pig, human or mouse skin are irradiated with a laser coincident with the peak absorption wavelength of nanoparticles (e.g., 1064 nm YAG laser for 1020 nm plasmonic particles) using clinical parameters (1 s exposure of 30-50 J/cm² and a pulse width of 10-50 ms). To determine microscopic photothermal damage of target skin structures such as the hair follicle and hair follicle bulge stem cells, at ten days after application and irradiation, human subjects receive lidocaine injections to numb treatment areas and skin is carefully excised and punched into sections along spot size demarcations. Fresh human skin biopsies or explanted human and animal skin samples are fixed in 10% paraformaldehyde, paraffin-embedded, and cut into 5-um sections on a microtome in transverse directions, or they are fixed in Zamboni’s solution with 2% picric acid and cryosectioned by freezing sliding microtome. Slides with mounted paraffin sections are deparaffinized and stained with hematoxylin and eosin (H&E). Histological sections are examined at various depths for markers of thermal damage and inflammation. Hematoxylin and eosin (H&E) is used to image skin and follicle microanatomy and indicate degeneration of hair shafts, atrophy of sebaceous glands, and cell vacuolization (indicating cellular damage). Nitro blue tetrazolium chloride (NBTC), a lactate dehydrogenase stain that is lost upon thermal injury to cells, is used to assess cellular damage in follicles of skin samples receiving plasmonic nanoparticle plus laser treatment is scored and compared to those receiving laser treatment alone. Live treated human skin areas are also followed clinically for 2 weeks to 3 months following plasmonic nanoparticle + laser treatment, or during repeated plasmonic nanoparticle + laser treatments, and compared to baseline digital photograph taken prior to first treatment, and to negative control laser only treatments. Clinical observations of hair removal, as well as erythema, edema, discomfort, irritation or scarring, are noted to determine degree of non-specific thermal damage.

Effect of plasmonic particle coating on specificity of delivery and photothermal heating. Preferentially, a matrix component such as silica, polystyrene or polyethylene glycol is provided in the formulation to improve particle stability and enable facile removal from the skin surface after application and follicle targeting. Acetone, ethanol, or a debriding agent can be used to remove all particles from the surface of the skin that have not deposited in the follicle, in order to reduce or prevent non-follicular heating of the skin. In Figure 5, live human skin was treated with Uncoated plasmonic nanoparticles compared to Silica-coated plasmonic particles, prior to laser-irradiation and comparison to no particle treatment (laser only) controls. Pre-treatment of skin, including shaving with razor and microdermabrasion (15 sec, medium setting) to remove hair-plugs and "open" the follicle for particle delivery, was performed on both forearms. Human forearm skin was irradiated with 810 nm laser pulses (30 J/cm², 30 ms, 2 passes) alone (Figure 5A), or after treatment with a formulation of 830 nm resonant, Uncoated plasmonic nanoparticles in 20% propylene glycol (Figure 5B). The plasmonic nanoparticle formulation was applied with 3 minute massage and repeated 3 times, and the skin surface wiped with 3 applications of alternative water and ethanol before laser irradiation. At 30 minutes following laser irradiation, non-specific clinical burns were observed due to significant photothermal heating of residual, Uncoated particles on the skin surface (Figure 5B). Live human skin was also irradiated with 1064 nm laser pulses (40 J/cm², 55 ms, 3 passes) alone (Figure 5C), or after treatment with a formulation of 1020 nm resonant, Silica-coated plasmonic nanoparticles in 20% propylene glycol (Figure 5D). The plasmonic nanoparticle formulation was applied with 3 minute massage and repeated 3 times, and the skin surface wiped with 3 applications of alternative water and ethanol before laser irradiation. At 30 minutes following laser irradiation, no evidence of burning of the skin or erythema was observed, as Silica-coated particles could be sufficiently wiped from the skin surface (Figure 5D). Magnified photography of the skin area treated with Silica-coated particles + Laser shows specific photothermal damage (perifollicular erythema and edema) in the nanoparticle-targeted site, without damage to surrounding or non-particle-treated tissues (Figure 6).

Provided herein are methods for using the compositions described herein for the treatment of acne vulgaris and other acnes and acne-like skin conditions, but the selective targeting of sebaceous follicles, particularly the sebaceous glands and/or hair follicles. Plasmonic nanoparticles generated and formulated as described above are introduced into a target tissue region, generally a skin region, and activated with laser-based systems as known in the art in order to achieve effective hair removal.

To achieve maximal penetration depth and concentration of plasmonic nanoparticles in the hair follicle and/or near the component of the sebaceous gland including the sebaceous duct, the sebum, the epithelial linking of the sebaceous gland, and/or near the bulge region including the stem cells, stem cell niche, epithelial lining of the bulge region, and/or near the follicular bulb, an optimal particle size of 100-800 nm containing one or several plasmonic nanoparticles is constructed. Nanoparticles encapsulating plasmonic nanoparticles can be formulated from any number of polymers or matrices. In some embodiments, the formulation contains a degradable or non-degradable polymer, e.g., synthetic polylactide/co-glycolide co-polymer, porous lauryllactame/caprolactame nylon co-polymer, hydroxyethylcellulose, poly-
electrolyte monolayers, or alternatively, in natural hydrogels such as hyaluronic acid, gelatin and others. In further embodiments, a hydrogel PLGA, PEG-acrylate is included in the formulation. Preferentially, a matrix component such as silica, polystyrene or polyethylene glycol is provided in the formulation to improve particle stability and enable facile removal from the skin surface after application and follicle targeting. Preferentially, formulations include surfactants (e.g. sodium dodecyl sulfate, sodium laureth 2-sulfate, ammonium lauryl sulfate, sodium octach-1/deceth-1 sulfate), components of a lipid bilayer, a liposome, or a microsome. Surfactants disrupt the epidermal skin barrier, emulsify sebum, improve mixing of hydrophilic nanoparticles with hydrophobic solutions, and reduce entropic barriers to delivering hydrophilic particles to hydrophobic regions of the skin (e.g. between the hair shaft and surrounding sheath or follicle). Plasmonic nanoparticles including nanorods, nanoshells, nanospheres, or nanorice can be encapsulated within the polymer nanoparticle or matrix or deposited on the particle surface. Alternatively, nanoparticles in the size range of 100-250 nm, 250-500 nm, 800 nm-1500 nm, or greater than 1500 nm can be used.

[0116] The use of physical or thermal force amplifies or expedites the penetration of light absorbing nanoparticles and conjugates thereof into hair follicles and/or sebaceous glands, in part by causing dilation of the hair follicle prior to application of the nanoparticles. For example, ultrasound and other sonic forces, mechanical vibrations, hair shaft manipulation (including pulling), physical force, thermal manipulation, and other treatments are utilized to improve entry of light-absorbing nanoparticles into hair follicles and/or sebaceous glands. Nanoparticle formulation treatments are performed alone, in combination, sequentially or repeated 1-24 times.

[0117] Prior to application of the plasmonic nanoparticles, a pre-treatment step of removing excess sebum from the surface of the skin may be performed using chemical and/or mechanical means. Pre-treatment of skin with mechanical or chemical exfoliation is used in some embodiments to remove hair-plugs and “open” the follicle for particle delivery. Additionally, hairs can be shaven or waxed to create a void in the hair follicle for particles to fill.

[0118] An applicator is used to uniformly apply the composition of nanoparticles into follicles. The applicator can be a sponge, a cloth, direct contact from a finger, a tube, a syringe, a device that applies suction, an aerosol, a spray, or other means known in the art. In one example, a formulation of 1 ml of plasmonic nanoparticles at a concentration of 100 O.D. with peak resonance of 810 nm is applied to approximately 200 cm² area of the skin of an adult human subject a sponge, a cloth, direct contact from a finger, a tube, a syringe, a device that applies suction, an aerosol, a spray, or other means known in the art. In one example, a formulation of 1 ml of plasmonic nanoparticles at a concentration of 100 O.D. with peak resonance of 810 nm is applied to approximately 200 cm² area of the skin of an adult human subject with a syringe. A cloth is used to evenly distribute solution across the skin area and into the hair follicles. Massage from a mechanical vibrator for 2 minutes with or without ultrasound at 1 MHz for 5 minutes is applied to drive particles deep into the follicle. Particles penetrate ~50% down the full length of the hair shaft at concentrations sufficient to heat skin in a 100um radius at incremental temperatures of 5-20-fold greater than is generated in similar volumes of adjacent skin when irradiated by a Diode (810 nm) laser. Acetone, ethanol, or a debiriding agent can be used to remove all particles from the surface of the skin that have not deposited in the follicle, in order to reduced or prevent non-follicular heating of the skin.

[0119] Delivery of plasmonic nanoparticles to the sebaceous gland determined using human abdominoplasty skin and dark field imaging. The human sebaceous gland exists within the pilosebaceous unit consisting of the hair, hair follicle, arrector pili muscle and sebaceous gland. In Figure 7A, a human skin biopsy is immunostained with antibodies against Collagen IV (basement membrane marker, blue) and PGP 9.5 (nerve marker, green) to visualize representative pilosebaceous unit microanatomy, including the hair follicle (HF), sebaceous gland (SG) and arrector pili muscle. To deliver nanoparticles to the hair follicle and sebaceous gland, skin was first pre-treated with shaving to remove extruding hair, microdermabrasion (15 sec, medium setting) to remove hair-plugs and comedocytes, and chemical depilation to “open” follicle microwells for particle delivery. A 100 O.D. suspension of plasmonic nanoparticles (200 nm diameter), formulated in 1% sodium dodecyl sulfate (SDS) and 20% propylene glycol (PG) was contacted with excised human abdominoplasty skin, after which excess nanoparticle suspension was removed and manual massage performed for three minutes, followed by ultrasound (1 MHz) for 5 minutes. The procedure was repeated for a total of 3 applications, and surface residue removed with 3-5 applications of alternating water and ethanol. The skin sample was excised, fixed, sectioned along horizontal planes and subjected to dark field imaging. As assessed by dark field imaging of horizontal skin sections, compositions of plasmonic nanoparticles with a cosmetically acceptable carrier of 1% SDS/20% PG administered with massage and ultrasound can be delivered 400-600 µm deep into the human follicle and specifically into the sebaceous gland (Figure 7B).

[0120] Cosmetic formulations for follicle and sebaceous gland delivery in human skin. Preferentially, formulations include surfactants (e.g. sodium dodecyl sulfate, sodium laureth 2-sulfate, ammonium lauryl sulfate, sodium octach-1/deceth-1 sulfate), components of a lipid bilayer, a liposome, or a microsome. Surfactants disrupt the epidermal skin barrier and emulsify the sebum to enable improved mixing of hydrophilic nanoparticles in hydrophobic solutions. Humectants such as propylene glycol are used to help improve topical viscosity and maintain physiological pH. To demonstrate the efficacy and mechanism of exemplary cosmetic formulations for human sebaceous gland delivery, skin was first pre-treated with shaving to remove extruding hair, microdermabrasion (15 sec, medium setting) to remove hair-plugs and comedocytes, and chemical depilation to “open” follicle microwells for particle delivery. Two separate 100 O.D. suspensions of plasmonic nanoparticles (200 nm diameter) were formulated in 1% sodium dodecyl sulfate and 20% propylene glycol (SDS/PD) or in 1% sodium laureth-2-sulfate and 20% propylene glycol (SLES/PD). Formulations were
contacted with two separate excised human abdominoplasty skin samples, and massage for 3 minutes followed by ultrasound (1 MHz) for 5 min was performed to drive particles deep into the follicles. The procedure was repeated for a total of 3 applications, and surface residue removed with 3-5 applications of alternating water and ethanol. The skin sample was excised, fixed, sectioned along horizontal planes and subjected to dark field imaging to assess particle delivery. As assessed by dark field imaging of horizontal skin sections, compositions of plasmonic nanoparticles with a cosmetically acceptable carrier of 1% SLES/20% administered with massage and ultrasound can be delivered 400-600 μm deep into the human follicle and specifically into the sebaceous gland (Figure 8B).

**[0121]** Impact of massage vs. ultrasound on nanoparticle delivery to human follicles and sebaceous gland. Ultrasound and other sonic forces, mechanical vibrations, hair shaft manipulation (including pulling), physical force, thermal manipulation, and other treatments are utilized to improve entry of light-absorbing nanoparticles into hair follicles and/or sebaceous glands. Mechanical massage improves follicular penetration through hair shaft 'pumping' mechanisms, while ultrasound enhances transdermal drug delivery through temporary disruption of the skin’s lipid bilayer, bubble formation, and liquid microstreaming. To characterize the effects of massage decoupled from ultrasound, skin was first pre-treated with shaving to remove extruding hair, microdermabrasion (15 sec, medium setting) to remove hair-plugs and comeocytes, and chemical depilation to "open" follicle microwells for particle delivery. A 100 O.D. suspension of plasmonic nanoparticles (200 nm diameter), formulated in 1% sodium dodecyl sulfate (SDS) and 20% propylene glycol (PG), was contacted with three separate excised human abdominoplasty skin samples. In the three treated human skin samples, massage only was performed for 3 minutes, ultrasound only (1 MHz) was performed for 5 minutes, or massage followed by ultrasound was performed to drive particles deep into the follicles. In a fourth sample, no particles were applied to skin. The procedure was repeated for a total of 3 applications, and surface residue removed with 3-5 applications of alternating water and ethanol. The skin sample was excised, fixed, sectioned along horizontal planes and subjected to dark field imaging to assess particle delivery. As assessed by dark field imaging of horizontal skin sections, compositions of plasmonic nanoparticles with a cosmetically acceptable carrier of 1% SLES/20% administered via ultrasound deliver more plasmonic nanoparticles to the infundibulum versus massage, albeit both mechanisms facilitate delivery (Figure 9).

**[0122]** Additional plasmonic nanoparticle formulations for follicle and sebaceous gland delivery in human skin. In some embodiments, plasmonic nanoparticles include nanorods, nanoshells, nanospheres, or nanorice, or plasmonic nanoparticles encapsulated within the polymer nanoparticle or matrix or deposited on the particle surface. Preferentially, a matrix component such as silica, polystyrene or polyethylene glycol is provided in the formulation to improve particle stability and enable facile removal from the skin surface after application and follicle targeting. To demonstrate the formulation of additional plasmonic nanoparticle shapes and concentrations for follicle, infundibulum, and sebaceous gland delivery, skin was first pre-treated with shaving to remove extruding hair, microdermabrasion (15 sec, medium setting) to remove hair-plugs and comeocytes, and chemical depilation to "open" follicle microwells for particle delivery. Separately, 10 O.D. suspensions of Silica-coated nanoplates, 30 O.D. suspensions of polyethylene-glycol coated plasmonic nanorods, and fluorescent silica particles were formulated in 1% sodium dodecyl sulfate and 20% propylene glycol. Formulations were contacted with three separate excised human abdominoplasty skin samples, and massage for 3 minutes followed by ultrasound (1 MHz) for 5 min was performed to drive particles deep into the follicles. The procedure was repeated for a total of 3 applications, and surface residue removed with 3-5 applications of alternating water and ethanol. The skin sample was excised, fixed, sectioned along horizontal planes and subjected to dark field imaging to assess particle delivery. As assessed by dark field imaging of horizontal skin sections, compositions of Polyethylene glycol (PEG)-coated nanorods (gold, 15 x 30 nm dimension) in cosmetically acceptable carrier, administered via ultrasound and massage, were observed within the follicle infundibulum at 200 um deep (Figure 10A). Compositions of plasmonic nanoparticles (Silica-coated nanoplates) at lower concentration (10 O.D.), were apparent at 400-600 um deep in the follicle and in the sebaceous gland (open arrow), albeit at lower concentration than comparable particles in a similar cosmetic carrier at 100 O.D. (Figure 10B).

**[0123]** Assessment of photothermal destruction of sebaceous gland and targeted skin structures. Nanoparticle formulations are tested in ex vivo animal skin samples, ex vivo human skin samples, and in vivo human skin as described in Example 3. One can measure efficacy of photothermal destruction at the nanoparticle accumulation site by measuring thermal damage to sebocytes and reduction in sebum production in the treated sebaceous follicles. To assess photothermal destruction, human skin is first pre-treated with shaving to remove extruding hair, microdermabrasion (15 sec, medium setting) to remove hair-plugs and comeocytes, and chemical depilation to "open" follicle microwells for particle delivery. Skin is contacted with a 100 O.D. suspension of 810 nm resonant plasmonic nanoparticles (200 nm diameter), and is massaged for 3 minutes followed by ultrasound (1 MHz) for 5 min to drive particles deep into the follicles. The procedure is repeated for a total of 3 applications, and surface residue removed with 3-5 applications of alternating water and ethanol. Treated human skin samples are laser irradiated with 810 nm laser (40 J/cm², 30 ms, 5 pulses), and compared to laser only treated human skin. Human skin is biopsied, fixed in Zamboni’s solution with 2% picric acid, and cryosectioned by freezing sliding microtome. Slides with mounted paraffin sections are deparaffinized and stained with hematoxylin and eosin (H&E). Histological sections are examined at various depths for markers of thermal damage and inflammation. Hematoxylin and eosin (H&E) is used to image skin and follicle microanatomy and indicate degeneration
of hair shafts, atrophy of sebaceous glands, and cell vacuolization (indicating cellular damage). Nitro blue tetrazolium chloride (NBTC), a lactate dehydrogenase stain that is lost upon thermal injury to cells, may also be used to assess damage to keratinocytes vs. sebocytes. An intracellular stain, Oil-Red-O, may be used to determine lipid and sebum oil content in treated samples. Sebum excretion rates are measured on in vivo skin at 1-3 months follow up using sebum-absorbant tapes to demonstrate functional change in sebum flow. Clearance and prevention of acne lesions is measured by patient reported outcomes and counting acne lesions at 1-3 months follow up.

Example 5. Formulation of thermoablative plasmonic nanoparticles for vascular ablation.

Formulations are prepared to maximize nanoparticle stability (degree of aggregation in solution), nanoparticle concentration, and nanoparticle absorbance (degree of laser-induced heating at different concentrations) once injected into the blood stream. Nanoparticles are generated as in Example 1 using an appropriate solvent. The mixture comprising a plurality of nanoparticles in water is concentrated to about 100-500 OD at peak absorbance and exchanged for a new solvent by liquid chromatography, a solvent exchange system, a centrifuge, precipitation, or dialysis. Typical exchange solvent is 0.15 mol/L NaCl, 0.1 mol/L Na phosphate buffer (pH 7.2).

Example 6. Use of plasmonic nanoparticles for thermoablation of component(s) of vessels and microvessels.

Nanoparticle-containing compositions are administered, typically intravascularly. Subsequent to such administration of plasmonic nanoparticles, a laser matched to the peak plasmonic resonance of the particles (e.g., 755nm, 810nm, or 1064nm) is applied to heat nanoparticles and surrounding tissue. Pulse widths of 10-100ns, 100ns-1ms, 1-10ms, 10-100ms, 100-1000ms or continuous wave irradiation is used to achieve thermal heat gradients and localized heating in the vicinity of particle or particles of 20-200nm, 200nm-2μm, 2-20μm, 20-200μm, 200μm -2mm. Thermal gradients of 20-200nm are achieved from individual particles. Supra millimeter thermal gradients are achieved by the collective heat deposition of many particles in veins with diameters of several hundred microns or more. Irradiation is applied from 1 pulse to many pulses over seconds to minutes. A cooling device for epidermal layers is used concomitant to irradiation to reduce pain and prevent thermal damage elsewhere. Laser position, fluence, wavelength, angle of incidence, pattern of irradiation is modified to achieve irradiation of vessels at specific depths between 0-10mm, while avoiding heating of non-target vasculature. Alternatively, laser or light is administered through fiber optic waveguide administered via a catheter to heat the particles in larger veins.

Assessment of thermal damage to component(s) of vessels, microvessels, or capillaries. Thirty minutes after application, target vessels and the surrounding supporting tissue (e.g. skin) are removed. Biopsies are fixed in 10% paraformaldehyde, paraffin-embedded, and cut into 5-um sections on a microtome in transverse directions. Slides with mounted paraffin sections are deparaffinized and stained with hematoxylin and eosin (H&E) or silver enhancement staining. Using H&E staining and light microscopy, one or several vessels, microvessels, and capillaries can be imaged. Scoring is performed for visible thermal damage of the vessel structures. Additionally, vessel staining (e.g. CD31 stain) is performed to clearly identify vascular structures within tissue samples.

Claims

1. A composition comprising a cosmetically acceptable carrier and a plurality of plasmonic nanoparticles in an amount of 10^9 to 10^10 nanoparticles per millilitre of composition, for use in a method of treating acne in a mammalian subject, wherein the plasmonic nanoparticles are selected from nanorods, nanoshells, nanospheres, nanoplates or nanorice that are encapsulated within a matrix formed of a matrix component selected from silica or polyethylene glycol, wherein said method comprises

   i) topically administering said composition to a skin surface of the subject;
   ii) providing penetration means to redistribute the plasmonic nanoparticles from the skin surface to a sebaceous gland;
   iii) washing the plasmonic nanoparticles from the skin surface;
   iv) causing irradiation of the skin surface by light and
   v) shedding the plasmonic nanoparticles from the sebaceous gland.

2. A method of removing hair from a mammalian subject, comprising the steps of
i) topically administering to a skin surface of the subject a composition comprising a cosmetically acceptable carrier and a plurality of plasmonic nanoparticles in an amount of \(10^9\) to \(10^{18}\) nanoparticles per milliliter of the composition, wherein the plasmonic nanoparticles are selected from nanorods, nanoshells, nanospheres, nanoplates or nanorice that are encapsulated within a matrix formed of a matrix component selected from silica or polyethylene glycol;

ii) providing penetration means to redistribute the plasmonic nanoparticles from the skin surface into a hair follicle;

iii) washing the plasmonic nanoparticles from the skin surface;

iv) causing irradiation of the skin surface by light; and

v) shedding the plasmonic nanoparticles from the hair follicle along with the damaged hair follicle.

3. The composition for use according to claim 1 or the method of claim 2, wherein the nanoparticles comprise silver or gold.

4. The composition for use or the method of claim 3, wherein the matrix component is silica.

5. The composition for use or the method of claim 3, wherein the matrix component is polyethylene glycol.

6. The composition for use or the method of claim 3, wherein the nanoparticles are metallic composites of silver and silica.

7. The composition for use or the method of claim 3, wherein the nanoparticles are polyethylene glycol-coated gold nanospheres.

8. The composition for use according to claim 1 or the method of claim 2, wherein the light source comprises excitation of mercury, xenon, deuterium, or a metal-halide, phosphorescence, incandescence, luminescence, light emitting diode, or sunlight.

9. The composition for use according to claim 1 or the method of claim 2, wherein the penetration means comprises high frequency ultrasound, low frequency ultrasound, massage, iontophoresis, high pressure air flow, high pressure liquid flow, vacuum, pre-treatment with fractionated photothermolysis or dermabrasion, or a combination thereof.

10. The composition for use according to claim 1 or the method of claim 2, wherein the irradiation comprises light having a wavelength of light between about 200 nm and about 10,000 nm, a fluence of about 1 to about 100 joules/cm², a pulse width of about 1 femtosecond to about 1 second, and a repetition frequency of about 1 Hz to about 1 THz.

11. The composition for use according to claim 1 or the method of claim 2, wherein the cosmetically acceptable carrier comprises an additive, a colorant, an emulsifier, a fragrance, a humectant, a polymerizable monomer, a stabilizer, a solvent, or a surfactant.

12. The composition for use of claim 7 or the method of claim 7, wherein the surfactant is selected from the group consisting of: sodium laureth 2-sulfate, sodium dodecyl sulfate, ammonium lauryl sulfate, sodium octech-1/deceth-1 sulfate, lipids, proteins, peptides or derivatives thereof.

13. The composition for use of claim 7 or the method of claim 7, wherein the cosmetically acceptable carrier comprises surfactant in an amount between about 0.1 and about 10.0% weight-to-weight of the carrier.

14. The composition for use of claim 7 or the method of claim 7, wherein the solvent is selected from the group consisting of water, propylene glycol, alcohol, hydrocarbon, chloroform, acid, base, acetone, diethyl-ether, dimethyl sulfoxide, dimethylformamide, acetonitrile, tetrahydrofuran, dichloromethane, and ethylacetate.

15. The composition for use according to claim 1 or the method of claim 2, wherein the plasmonic nanoparticles have a particle size in the range of from about 1 nm to about 1000 nm.

16. The composition for use according to claim 1 or the method of claim 2, wherein the plasmonic nanoparticles have an optical density of at least about 1 O.D at one or more peak resonance wavelengths.

17. The composition for use according to claim 1 or the method of claim 2, wherein the plasmonic nanoparticles have an optical density of 10 O.D - 1,000 O.D at one or a plurality of peak resonance wavelengths.
18. The composition for use according to claim 1 or the method of claim 2, wherein the light has a wavelength selected from the group consisting of: 755 nm, 800 - 810 nm, and 1064 nm.

19. The composition for use according to claim 1 or the method of claim 2, wherein said method further comprises pre-treating the skin surface to increase delivery of the plasmonic nanoparticles from the skin surface to the component of dermal tissue, wherein pre-treatment comprises at least one of the group consisting of hair removal via shaving, waxing, cyanoacrylate surface peels, calcium thioglycolate treatment, or other techniques to remove the hair shaft and/or hair follicle plugs, and exfoliation.

20. The composition for use according to claim 1 or the method of claim 2, wherein the plasmonic nanoparticles comprise silver, gold, nickel, copper, titanium, silicon, galadum, palladium, platinum or chromium.

21. The composition for use according to claim 1 or the method of claim 2, wherein said plurality of plasmonic nanoparticles is present in a quantity of $10^{11}$ to $10^{13}$ nanoparticles per millilitre of the composition.

22. The composition for use according to claim 1, wherein the plasmonic nanoparticles are silver nanoplates, wherein the nanoplate has a dimension in a range of 100-250 nm, wherein the coating is a hydrophilic, silica coating, wherein said plurality of plasmonic nanoparticles is present in a quantity of $10^{11}$ to $10^{13}$ nanoparticles per millilitre of the composition, wherein the plasmonic nanoparticles are unassembled, wherein the unassembled plasmonic nanoparticles are not bound to each other through a physical force or chemical bond either directly or indirectly through an intermediary, wherein the irradiation comprises light having a wavelength of light selected from the group consisting of: 755 nm, 800-810 nm, and 1064 nm.

23. The composition for use according to claim 1, wherein the plasmonic nanoparticles comprise gold, wherein the coating is a hydrophilic, polyethylene glycol coating, wherein said plurality of plasmonic nanoparticles is present in a quantity of $10^{11}$ to $10^{13}$ nanoparticles per millilitre of the composition, wherein the plasmonic nanoparticles are unassembled, wherein the unassembled plasmonic nanoparticles are not bound to each other through a physical force or chemical bond either directly or indirectly through an intermediary, wherein the irradiation comprises light having a wavelength of light selected from the group consisting of: 755 nm, 800-810 nm, and 1064 nm.

24. The method of claim 2, wherein the plasmonic nanoparticles are silver nanoplates, wherein the nanoplate has a dimension in a range of 100-250 nm, wherein the coating is a hydrophilic, silica coating, wherein said plurality of plasmonic nanoparticles is present in a quantity of $10^{11}$ to $10^{13}$ nanoparticles per millilitre of the composition, wherein the plasmonic nanoparticles are unassembled, wherein the unassembled plasmonic nanoparticles are not bound to each other through a physical force or chemical bond either directly or indirectly through an intermediary, wherein the irradiation comprises light having a wavelength of light selected from the group consisting of: 755 nm, 800-810 nm, and 1064 nm.

25. The method of claim 2, wherein the plasmonic nanoparticles comprise gold, wherein the coating is a hydrophilic, polyethylene glycol coating, wherein said plurality of plasmonic nanoparticles is present in a quantity of $10^{11}$ to $10^{13}$ nanoparticles per millilitre of the composition, wherein the plasmonic nanoparticles are unassembled, wherein the unassembled plasmonic nanoparticles are not bound to each other through a physical force or chemical bond either directly or indirectly through an intermediary, wherein the irradiation comprises light having a wavelength of light selected from the group consisting of: 755 nm, 800-810 nm, and 1064 nm.
Patentansprüche

1. Zusammensetzung, umfassend einen kosmetisch verträglichen Träger und eine Vielzahl von plasmonischen Nanopartikeln in einer Menge von $10^9$ bis $10^{18}$ Nanopartikeln pro Milliliter der Zusammensetzung, zur Verwendung in einem Verfahren zur Behandlung von Akne bei einem Säugersubjekt, wobei die plasmonischen Nanopartikel ausgewählt sind aus Nanostäbchen, Nanoschalen, Nanosphären, Nanoplättchen oder Nanoreis, die innerhalb einer Matrix verkapselt sind, die aus einer aus Siliziumdioxid oder Polyethylenlykol ausgewählten Matrixkomponente gebildet ist, wobei das Verfahren umfasst

i) topisches Verabreichen der Zusammensetzung an eine Hautoberfläche des Subjekts;
ii) Bereitstellen eines Penetrationsmittels zur Umverteilung der plasmonischen Nanopartikel von der Hautoberfläche zu einer Talgdrüse;
iii) Abwaschen der plasmonischen Nanopartikel von der Hautoberfläche;
iv) Bewirken einer Bestrahlung der Hautoberfläche durch Licht und
v) Ausstoßen der plasmonischen Nanopartikel aus der Talgdrüse.

2. Verfahren zum Entfernen von Haar von einem Säugersubjekt, umfassend die folgenden Schritte:

i) topisches Verabreichen, an eine Hautoberfläche des Subjekts, einer Zusammensetzung umfassend einen kosmetisch verträglichen Träger und eine Vielzahl von plasmonischen Nanopartikeln in einer Menge von $10^9$ bis $10^{18}$ Nanopartikeln pro Milliliter der Zusammensetzung, wobei die plasmonischen Nanopartikel ausgewählt sind aus Nanostäbchen, Nanoschalen, Nanosphären, Nanoplättchen oder Nanoreis, die innerhalb einer Matrix verkapselt sind, die aus einer aus Siliziumdioxid oder Polyethylenlykol ausgewählten Matrixkomponente gebildet ist;
ii) Bereitstellen eines Penetrationsmittels zur Umverteilung der plasmonischen Nanopartikel von der Hautoberfläche in ein Haarfollikel;
iii) Abwaschen der plasmonischen Nanopartikel von der Hautoberfläche;
iv) Bewirken einer Bestrahlung der Hautoberfläche durch Licht; und
v) Ausstoßen der plasmonischen Nanopartikel aus dem Haarfollikel zusammen mit dem geschädigten Haarfollikel.

3. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei die Nanopartikel Silber oder Gold umfassen.

4. Zusammensetzung zur Verwendung oder Verfahren nach Anspruch 3, wobei die Matrixkomponente Siliziumdioxid ist.

5. Zusammensetzung zur Verwendung oder Verfahren nach Anspruch 3, wobei die Matrixkomponente Polyethylenlykol ist.

6. Zusammensetzung zur Verwendung oder Verfahren nach Anspruch 3, wobei die Nanopartikel metallische Verbundstoffe aus Silber und Siliziumdioxid sind.

8. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei die Lichtquelle die Anregung von Quecksilber, Xenon, Deuterium oder eines Metallhalids, Phosphoreszenz, Inkandeszenz, Lumineszenz, eine Leuchtdiode oder Sonnenlicht umfasst.

10. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei die Bestrahlung Licht mit einer Lichtwellenlänge zwischen etwa 200 nm und etwa 10.000 nm, einen Lichtfluss von etwa 1 bis etwa 100 Joule/cm², eine Pulsweite von etwa 1 Femtosekunde bis etwa 1 Sekunde und eine Wiederholungsfrequenz...
von etwa 1 Hz bis etwa 1 THz umfasst.

11. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei der kosmetisch verträgliche Träger einen Zusatzstoff, einen Farbstoff, einen Emulgator, einen Duftstoff, ein Feuchthaltemittel, ein polymerisierbares Monomer, einen Stabilisator, ein Lösungsmittel oder einen grenzflächenaktiven Stoff umfasst.

13. Zusammensetzung zur Verwendung nach Anspruch 7 oder Verfahren nach Anspruch 7, wobei der kosmetisch verträgliche Träger einen grenzflächenaktiven Stoff in einer Menge zwischen etwa 0,1 und etwa 10,0 % w/w des Trägers umfasst.

15. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei die plasmonischen Nanopartikel eine Partikelgröße im Bereich von etwa 1 nm bis etwa 1000 nm aufweisen.

16. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei die plasmonischen Nanopartikel eine optische Dichte von mindestens etwa 1 O.D bei einer oder mehreren Resonanz-Peak-Wellenlängen aufweisen.

17. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei die plasmonischen Nanopartikel eine optische Dichte von 10 O.D - 1.000 O.D. bei einer oder einer Vielzahl von Resonanz-Peak-Wellenlängen aufweisen.

18. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei das Licht eine Wellenlänge aufweist, die ausgewählt ist aus der Gruppe bestehend aus: 755 nm, 800 - 810 nm und 1064 nm.

19. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei das Verfahren ferner eine Vorbehandlung der Hautoberfläche umfasst, um die Abgabe der plasmonischen Nanopartikel von der Hautoberfläche an die Komponenten des dermalen Gewebes zu erhöhen, wobei die Vorbehandlung mindestens eine(s) der Vorbehandlung bestehend aus Haarentfernung durch Rasieren, Wachsen, Oberflächen-Peelings mit Cyanacrylat, Behandlung mit Calciumthioglykolat oder anderen Techniken zur Entfernung des Haarshafts und/oder der Haarfollikel-Stopfen und Exfoliation umfasst.

21. Zusammensetzung zur Verwendung nach Anspruch 1 oder Verfahren nach Anspruch 2, wobei die Vielzahl von plasmonischen Nanopartikeln in einer Menge von 10^{11} bis 10^{13} Nanopartikeln pro Milliliter der Zusammensetzung vorliegt.

22. Zusammensetzung zur Verwendung nach Anspruch 1, wobei die plasmonischen Nanopartikel Silber-Nanoplättchen sind, wobei das Nanoplätchen ein Maß in einem Bereich von 100-250 nm aufweist, wobei die Beschichtung eine hydrophile Siliziundioxidbeschichtung ist, wobei die Vielzahl von plasmonischen Nanopartikeln in einer Menge von 10^{11} bis 10^{13} Nanopartikeln pro Milliliter der Zusammensetzung vorliegt, wobei die plasmonischen Nanopartikel nicht assembliert sind, wobei die nicht assemblierten plasmonischen Nanopartikel nicht durch eine physikalische Kraft oder chemische Bindung entweder direkt oder indirekt durch einen Vermittler aneinander gebunden sind, wobei die Bestrahlung Licht mit einer Lichtwellenlänge umfasst, die ausgewählt ist aus der Gruppe bestehend aus: 755 nm, 800-810 nm und 1064 nm.
23. Zusammensetzung zur Verwendung nach Anspruch 1,
   wobei die plasmonischen Nanopartikel Gold umfassen,
   wobei die Beschichtung eine hydrophile Polyethylenglykolbeschichtung ist,
   wobei die Vielzahl von plasmonischen Nanopartikeln in einer Menge von $10^{11}$ bis $10^{13}$ Nanopartikeln pro Milliliter
der Zusammensetzung vorliegt,
   wobei die plasmonischen Nanopartikel nicht assembliert sind, wobei die nicht assemblierten plasmonischen Nano-
   partikel nicht durch eine physikalische Kraft oder chemische Bindung entweder direkt oder indirekt durch einen
   Vermittler aneinander gebunden sind,
   wobei die Bestrahlung Licht mit einer Lichtwellenlänge umfasst, die ausgewählt ist aus der Gruppe bestehend aus:
   755 nm, 800-810 nm und 1064 nm.

24. Verfahren nach Anspruch 2,
   wobei die plasmonischen Nanopartikel Silber-Nanoplättchen sind,
   wobei das Nanoplättchen ein Maß in einem Bereich von 100-250 nm aufweist,
   wobei die Beschichtung eine hydrophile Siliziumdioxidbeschichtung ist,
   wobei die Vielzahl von plasmonischen Nanopartikeln in einer Menge von $10^{11}$ bis $10^{13}$ Nanopartikeln pro Milliliter
der Zusammensetzung vorliegt,
   wobei die plasmonischen Nanopartikel nicht assembliert sind, wobei die nicht assemblierten plasmonischen Nano-
   partikel nicht durch eine physikalische Kraft oder chemische Bindung entweder direkt oder indirekt durch einen
   Vermittler aneinander gebunden sind,
   wobei die Bestrahlung Licht mit einer Lichtwellenlänge umfasst, die ausgewählt ist aus der Gruppe bestehend aus:
   755 nm, 800-810 nm und 1064 nm.

25. Verfahren nach Anspruch 2,
   wobei die plasmonischen Nanopartikel Gold umfassen,
   wobei die Beschichtung eine hydrophile Polyethylenglykolbeschichtung ist,
   wobei die Vielzahl von plasmonischen Nanopartikeln in einer Menge von $10^{11}$ bis $10^{13}$ Nanopartikeln pro Milliliter
der Zusammensetzung vorliegt,
   wobei die plasmonischen Nanopartikel nicht assembliert sind, wobei die nicht assemblierten plasmonischen Nano-
   partikel nicht durch eine physikalische Kraft oder chemische Bindung entweder direkt oder indirekt durch einen
   Vermittler aneinander gebunden sind,
   wobei die Bestrahlung Licht mit einer Lichtwellenlänge umfasst, die ausgewählt ist aus der Gruppe bestehend aus:
   755 nm, 800-810 nm und 1064 nm.

Revendications

1. Composition comprenant un support acceptable sur le plan cosmétique et une pluralité de nanoparticules plasmo-
   niques dans une quantité de $10^9$ à $10^{18}$ nanoparticules par millilitre de composition, destinée à être utilisée dans
   un procédé de traitement de l’acné chez un sujet mammalien,
   dans laquelle les nanoparticules plasmoniques sont sélectionnées parmi des nanotiges, des nanocoques, des
   nanosphères, des nanoplaques ou des nanoriz qui sont encapsulés au sein d’une matrice formée d’un composant
de matrice sélectionné parmi la silice ou le polyéthylène glycol, dans laquelle le dit procédé comprend

1) l’administration par voie topique de ladite composition à une surface cutanée du sujet ;
2) la fourniture d’un moyen de pénétration pour redistribuer les nanoparticules plasmoniques de la surface
cutanée à une glande sébacée ;
3) le lavage des nanoparticules plasmoniques de sur la surface cutanée ;
4) le fait de provoquer l’irradiation de la surface cutanée par la lumière et
5) l’élimination des nanoparticules plasmoniques de la glande sébacée.

2. Procédé d’enlèvement de poils d’un sujet mammalien, comprenant les étapes

1) d’administration par voie topique à une surface cutanée du sujet d’une composition comprenant un support
   acceptable d’un point de vue cosmétique et d’une pluralité de nanoparticules plasmoniques dans une quantité
   de $10^9$ à $10^{18}$ nanoparticules par millilitre de la composition, dans lequel les nanoparticules plasmoniques sont
   sélectionnées parmi des nanotiges, des nanocoques, des nanosphères, des nanoplaques ou des nanoriz qui
   sont encapsulés au sein d’une matrice formée d’un composant de matrice sélectionné parmi la silice ou le
polyéthylène glycol ;
ii) de fourniture d’un moyen de pénétration pour redistribuer les nanoparticules plasmoniques depuis la surface cutanée jusque dans un follicule pileux ;
iii) de lavage des nanoparticules plasmoniques de sur la surface cutanée ;
iv) d’irradiation de la surface cutanée par la lumière ; et
v) d’élimination des nanoparticules plasmoniques du follicule pileux ainsi que du follicule pileux endommagé.

3. Composition destinée à l’utilisation selon la revendication 1, ou procédé de la revendication 2, dans lequel les nanoparticules comprennent de l’argent ou de l’or.

4. Composition destinée à être utilisée ou procédé de la revendication 3, dans lequel le composant de matrice est la silice.

5. Composition destinée à être utilisée ou procédé de la revendication 3, dans lequel le composant de matrice est le polyéthylène glycol.

6. Composition destinée à être utilisée ou procédé de la revendication 3, dans lequel les nanoparticules sont des composites métalliques d’argent et de silice.

7. Composition destinée à être utilisée ou procédé de la revendication 3, dans lequel les nanoparticules sont des nanosphères d’or revêtues de polyéthylène glycol.

8. Composition destinée à être utilisée selon la revendication 1 ou procédé de la revendication 2, dans lequel la source de lumière comprend l’excitation de mercure, de xénon, de deutérium, ou d’un halogénure métallique, la phosphorescence, l’incandescence, la luminescence, une diode émettrice de lumière, ou la lumière du soleil.

9. Composition destinée à être utilisée selon la revendication 1 ou procédé de la revendication 2, dans lequel le moyen de pénétration comprend l’ultrason haute fréquence, l’ultrason basse fréquence, le massage, l’iontophorese, l’écoulement d’air sous haute pression, l’écoulement de liquide sous haute pression, le vide, un prétraitement par photothermolyse fractionnée ou dermabrasion, ou une combinaison de ceux-ci.

10. Composition destinée à être utilisée selon la revendication 1 ou procédé selon la revendication 2, dans lequel l’irradiation comprend une lumière ayant une longueur d’onde de lumière entre environ 200 nm et environ 10 000 nm, une fluence d’environ 1 à environ 100 joules/cm², une largeur d’impulsion d’environ 1 femtoseconde à environ 1 seconde, et une fréquence de répétition d’environ 1 Hz à environ 1 THz.

11. Composition destinée à être utilisée selon la revendication 1 ou procédé de la revendication 2, dans lequel le support acceptable d’un point de vue cosmétique comprend un additif, un colorant, un émulsifiant, un parfum, un humidifiant, un monomère polymérisable, un stabilisant, un solvant, ou un tensioactif.

12. Composition destinée à être utilisée selon la revendication 7 ou procédé de la revendication 7, dans lequel le tensioactif est sélectionné dans le groupe constitué par : le laureth 2-sulfate de sodium, le dodécylsulfate de sodium, le laurylsulfate d’ammonium, l’octech-1/déceth-1 sulfate de sodium, des lipides, des protéines, des peptides ou des dérivés de ceux-ci.

13. Composition destinée à être utilisée selon la revendication 7 ou procédé de la revendication 7, dans lequel le support acceptable d’un point de vue cosmétique comprend un tensioactif dans une quantité située entre 0,1 et environ 10,0 % poids pour poids du support.

14. Composition destinée à être utilisée selon la revendication 7 ou procédé de la revendication 7, dans lequel le solvant est sélectionné parmi le groupe constitué par : l’eau, le propylène glycol, un alcool, un hydrocarbure, du chloroforme, un acide, une base, l’acétone, l’éther diéthyle, le diméthylsulfoxide, le diméthylformamide, l’acétonitrile, le tétrahydrofurane, le dichlorométhane, et l’acétate d’éthyle.

15. Composition destinée à être utilisée selon la revendication 1 ou procédé de la revendication 2, dans lequel les nanoparticules plasmoniques ont une taille de particules dans la plage d’environ 1 nm à environ 1 000 nm.

16. Composition destinée à être utilisée selon la revendication 1 ou procédé de la revendication 2, dans lequel les
nanoparticules plasmoniques ont une densité optique d’au moins environ 1 O. D. à une ou plusieurs longueurs d’onde de résonnance de crête.

17. Composition destinée à être utilisée selon la revendication 1 ou procédé de la revendication 2, dans lequel les nanoparticules plasmoniques ont une densité optique de 10 O. D. à 1 000 O. D. à une ou plusieurs longueurs d’onde de résonnance de crête.

18. Composition destinée à être utilisée selon la revendication 1 ou procédé de la revendication 2, dans lequel la lumière a une longueur d’onde sélectionnée dans le groupe constitué par : 755 nm, 800 à 810 nm, et 1 064 nm.

19. Composition destinée à être utilisée selon la revendication 1 ou procédé de la revendication 2, dans lequel le prétraitement comprend en outre le prêtraitement de la surface cutanée pour augmenter la libération des nanoparticules plasmoniques de la surface cutanée au composant du tissu dermique, dans lequel le prétraitement comprend au moins un élément du groupe constitué par l’élimination de poils par rasage, l’épilation à la cire, l’arrachement en surface avec des cyanacrylates, le traitement au thioglycolate de calcium, ou d’autres techniques pour éliminer la tige pileuse et/ou les bouchons de follicules pileux, et l’exfoliation.

20. Composition destinée à être utilisée selon la revendication 1 ou procédé selon la revendication 2, dans lequel les nanoparticules plasmoniques comprennent l’argent, l’or, le nickel, le cuivre, le titane, le silicium, le galadum, le palladium, le platine ou le chrome.

21. Composition destinée à être utilisée selon la revendication 1 ou procédé de la revendication 2, dans lequel ladite pluralité de nanoparticules plasmoniques est présente dans une quantité de 10^{11} à 10^{13} nanoparticules par millilitre de la composition.

22. Composition destinée à être utilisée selon la revendication 1, dans laquelle les nanoparticules plasmoniques sont des nanoplaques d’argent, dans laquelle la nanoplaque a une dimension dans une plage de 100 à 250 nm, dans laquelle le revêtement est un revêtement de silice, hydrophile, dans laquelle ladite pluralité de nanoparticules plasmoniques est présente dans une quantité de 10^{11} à 10^{13} nanoparticules par millilitre de la composition, dans laquelle les nanoparticules plasmoniques non assemblées ne sont pas liées les unes aux autres par une force physique ou une liaison chimique soit directement ou indirectement par un intermédiaire, dans laquelle l’irradiation comprend une lumière ayant une longueur d’onde de lumière sélectionnée dans le groupe constitué par : 755 nm, 800 à 810 nm, et 1 064 nm.

23. Composition destinée à être utilisée selon la revendication 1, dans laquelle les nanoparticules plasmoniques comprennent de l’or, dans laquelle le revêtement est un revêtement de polyéthylène glycol, hydrophile, dans laquelle ladite pluralité de nanoparticules plasmoniques est présente dans une quantité de 10^{11} à 10^{13} nanoparticules par millilitre de la composition, dans laquelle les nanoparticules plasmoniques non assemblées ne sont pas liées les unes aux autres par une force physique ou une liaison chimique soit directement ou indirectement par un intermédiaire, dans laquelle l’irradiation comprend une lumière ayant une longueur d’onde de lumière sélectionnée dans le groupe constitué par : 755 nm, 800 à 810 nm, et 1 064 nm.

24. Procédé de la revendication 2, dans lequel les nanoparticules plasmoniques sont des nanoplaques d’argent, dans lequel la nanoplaque a une dimension dans une plage de 100 à 250 nm, dans lequel le revêtement est un revêtement de silice, hydrophile, dans lequel ladite pluralité de nanoparticules plasmoniques est présente dans une quantité de 10^{11} à 10^{13} nanoparticules par millilitre de la composition, dans lequel les nanoparticules plasmoniques non assemblées, dans lequel les nanoparticules plasmoniques non assemblées ne sont pas liées les unes aux autres par une force physique ou une liaison chimique soit directement ou indirectement par un intermédiaire, dans lequel l’irradiation comprend une lumière ayant une longueur d’onde de lumière sélectionnée dans le groupe
25. Procédé de la revendication 2,
dans lequel les nanoparticules plasmoniques comprennent de l’or,
dans lequel le revêtement est un revêtement de polyéthylène glycol, hydrophile,
dans lequel ladite pluralité de nanoparticules plasmoniques est présente dans une quantité de $10^{11}$ à $10^{13}$ nano-
particules par millilitre de la composition,
dans lequel les nanoparticules plasmoniques sont non assemblées, dans laquelle les nanoparticules plasmoniques non assemblées ne sont pas liées les unes aux autres par une force physique ou une liaison chimique soit directement
ou indirectement par un intermédiaire,
dans lequel l’irradiation comprend une lumière ayant une longueur d’onde de lumière sélectionnée dans le groupe constitué par : 755 nm, 800 à 810 nm, et 1 064 nm.
FIG. 1

A. Topical formulation for hair removal

B. Topical formulation for acne treatment
FIG. 2

- SL-001
- Carbon lotion
- Meladine spray
- Indocyanine green

Temperature (°C)

Clinical Laser (# of pulses)
FIG. 3

A

Follicle + fluorescent particles, sectioned vertically

plane 1

plane 2

B

C

plane 1

plane 2

50 µm
FIG. 4

A
Follicle + plasmonic particles, sectioned horizontally

B

C
Negative Control
FIG. 5

Left Forearm: Laser Only (Control)

Right Forearm: Particles + Laser Treatment

Uncoated particles

Silica-coated particles
FIG. 7
FIG. 9

A  After Massage  B  After Ultrasound

Low mag  (20x)  

High mag  (50x)  

100 μm  100 μm  40 μm  40 μm
FIG. 10

A. PEG-coated nanorods

B. Silica-coated nanoplates

Particles at 200 μm deep

Particles at 600 μm deep

100 μm
