NEW PEPTIDE DERIVATIVES

This invention relates to new competitive inhibitors of trypsin-like serine proteases, especially thrombin and kininogenses such as kallikrein, their synthesis, pharmaceutical compositions containing the compounds as active ingredients, and the use of the compounds as thrombin inhibitors and anticoagulants and as antiinflammatory inhibitors, respectively. The invention also relates to novel use of compounds as starting materials in synthesis of a serine protease inhibitor. Furthermore the invention relates to a novel structural fragments in serine protease inhibitors.

BACKGROUND

Blood coagulation is the key process involved in both haemostasis (i.e. prevention of blood loss from a damaged vessel) and thrombosis (i.e. the pathological occlusion of a blood vessel by a blood clot). Coagulation is the result of a complex series of enzymatic reactions, where one of the final steps is conversion of the proenzyme prothrombin to the active enzyme thrombin.

Thrombin plays a central role in coagulation. It activates platelets, it converts fibrinogen into fibrin monomers, which polymerise spontaneously into filaments, and it activates factor XIII, which in turn crosslinks the polymer to insoluble fibrin. Thrombin further activates factor V and factor VIII in a positive feedback reaction. Inhibitors of thrombin are therefore expected to be effective anticoagulants by inhibition of platelets, fibrin formation and fibrin stabilization. By inhibiting the positive feedback mechanism they are expected to exert inhibition early in the chain of events leading to coagulation and thrombosis.

Kininogenses are serine proteases that act on kininogens to produce kinins (bradykinin, kallidin, and Met-Lys-bradykinin). Plasma kallikrein, tissue kallikrein, and mast cell tryptase represent important kininogenses.

Kinin (bradykinin, kallidin) are generally involved in inflammation. For example, the active inflammation process is associated with increased permeability of the blood vessels resulting in extravasation of plasma into the tissue. The ensuing plasma exudate contains all the protein systems of circulating blood. The plasma-derived kininogens inevitably will be interacting with different kallikreins, forming kinins continually as long as the active plasma exudation process is ongoing. Plasma exudation occurs independent of the mechanisms that are involved in the inflammation, whether it is allergy, infection or other factors (Persson et al., Editorial, Thorax, 1992, 47:993-1000).

Plasma exudate is thus a feature of many diseases including asthma, rhinitis, common cold, and inflammatory bowel diseases. Particularity in allergy mast cell tryptase will be released (Salomonson et al., Am. Rev. Respir. Dis., 1992, 146:1555-1542) to contribute to kinin formation and other pathogenic events in asthma, rhinitis, and intestinal diseases.

The kinins are biologically highly active substances with smooth muscle effects, secretory effects, neurogenic effects, and actions that may perpetuate inflammatory processes including activation of phospholipase A2 and increasing vascular permeability. The latter action potentially induces a vicious circle with kinins providing for the generation of more kinins etc.

Tissue kallikrein cleaves primarily low molecular weight kininogen to produce kallidin and plasma kallikrein preferably releases bradykinin from high molecular weight kininogen.

PRIOR ART

Inhibitors of thrombin based on the amino acid sequence around the cleavage site for the fibrinogen A2 chain were first reported by Blomback et al. in J. Clin. Lab. Invest. 24, suppl 107, 59, (1969), who suggested the sequence Phe-Val-Arg (P9-P2-P1, herein referred to as the P3-P2-P1 sequence) to be the best inhibitor.

In U.S. Pat. No. 4,346,078 has S. Bajusz et al. described the thrombin inhibitor H-DPhe-Pro-Agm, a dipeptidyl derivative with an aminomethyl guanidine in the P1-position.

Inhibitors of thrombin based on peptide derivatives with a cyclic aminomethyl guanidine, e.g. 3-aminomethyl-1-amidinopiperidine, in the P1-position have been disclosed in EP-A2-0,468,231.

In EP-A2-0,185,390 has S. Bajusz et al. disclosed that replacing the agmatine with an arginine aldehyde gave a thrombin inhibitor which had much higher potency.

Inhibitors of kallikrein based on the amino acid sequence around the cleavage site Arg-Ser have been reported earlier.

The arginine chloromethyl ketones H-DPro-Phe-Arg-CH2Cl and H-D Phe-Phe-Arg-CH2Cl were reported as plasma kallikrein inhibitors by Kettner and Shaw in Biochemistry 1978, 17:4778-4784 and Meth. Enzym. 1981, 80:826-842.

Likewise, esters and amides containing the H-DPro-Phe-Arg sequence were reported by Farace et al. in Am. N.Y. Acad. Sci. 1981, 370:765-784 to be plasma kallikrein inhibitors.

Inhibitors of serine proteases that are based on electrophilic ketones instead of aldehydes in the P1-position are described in the following patent documents:

Inhibitors of trypsin-like serine proteases, such as thrombin and kallikrein, based on C-terminal boronic acid derivatives of arginine and isothiouronium analogues thereof have been revealed in EP-A2-0,293,881.

WO 92/04371 describing kininogense inhibitors, e.g. kallikrein inhibitors based on derivatives of arginine.

DISCLOSURE OF THE INVENTION

An object of the present invention is to provide novel and potent trypsin-like serine protease inhibitors, especially anticoagulantia and antiinflammatory compounds with competitive inhibitory activity towards their enzyme i.e. causing reversible inhibition. More specifically anticoagulantia for prophylaxis and treatment of thromboembolic
diseases such as venous thrombosis, pulmonary embolism, arterial thrombosis, in particular myocardial infarction and cerebral thrombosis, general hypercoagulable states and local hypercoagulable states, e.g. following angioplasty and coronary bypass operations, and other situations where thrombin is believed to play a role, e.g. Alzheimer's disease, as well as inhibition of kininogenases for treatment of inflammatory disorders e.g. asthma, rhinitis, urticaria, inflammatory bowel disease, and arthritis. A further object is to obtain thrombin inhibitors which are orally bioavailable and selective in inhibiting thrombin over other serine proteases. A further object of the invention is to obtain kininogenase inhibitors which can be given orally, rectally, topically e.g. dermally, or via the inhalation route.

[0523] Medical and Pharmaceutical Use

[0524] The invention also provides compositions and methods for the treatment, in a human or animal organism, of conditions where inhibition of thrombin is required and of physiologically disorders especially inflammatory diseases.

[0525] The thrombin inhibiting compounds of the invention are expected to be useful in particular in animals including man in treatment or prophylaxis of thrombosis and hypercoagulability in blood and tissues. They are furthermore expected to be useful in situation where there is an undesirable excess of the thrombin without signs of hypercoagulability, for example as in Alzheimer disease and pancreatitis. Disease states in which these compounds have a potential utility, in treatment and/or prophylaxis, include venous thrombosis and pulmonary embolism, arterial thrombosis, such as in myocardial infarction, unstable angina, thrombosis-based stroke and peripheral arterial thrombus and systemic embolism usually from the atrium during arterial fibrillation or from the left ventricle after transmural myocardial infarction. Further, these compounds have expected utility in prophylaxis of atherosclerotic diseases such as coronary arterial disease, cerebral arterial disease and peripheral arterial disease. Further, these compounds are expected to have synergistic antithrombotic effects when combined with any antithrombotic agent with a different mechanism of action, such as the antiplatelet agent acetylsalicylic acid. Further, these compounds are expected to be useful together with thrombolytics in thrombotic diseases, in particular myocardial infarction. Further, these compounds have expected utility in prophylaxis for re-occlusion after thrombolysis, percutaneous trans-luminal angioplasty (PTCA) and coronary bypass operations. Further, these compounds have expected utility in prevention of re-thrombosis after microsurgery and vascular surgery in general. Further, these compounds have expected utility in treatment and prophylaxis of disseminated intravascular coagulation caused by bacteria, multiple trauma, intoxication or any other mechanism. Further, these compounds are expected to be useful in anticoagulant treatment when blood is in contact with foreign surfaces in the body such as vascular grafts, vascular stents, vascular catheters, mechanical and biological prosthetic or any other medical device. Further, these compounds have expected utility in anticoagulant treatment when blood is in contact with medical devices outside the body such as during cardiovascular surgery using or heart-lung machine or in haemodialysis.

standard. The $^2$H chemical shifts in D$_2$O are relative to the sodium salt of 3-(trimethylsilyl)-1-$d_2$-propanoic acid and the $^{13}$C chemical shifts in D$_2$O are referenced relative to 1,4-dioxane (67.3 ppm), both as external standard. Calibrating with an external standard may in some cases cause minor shift differences compared to an internal standard, however, the difference in $^2$H chemical shift is less than 0.02 ppm and in $^{13}$C less than 0.1 ppm.

[0578] The $^1$H NMR spectrum of peptide sequences containing a proline or a "proline like" residue frequently exhibits two sets of resonances. This corresponds to the existence of two contributing conformers with respect to the rotation around the amide bond, where proline is the N-part of the amide bond. The conformers are named cis and trans. In our compounds the sequences (R)Cha-Aze-, (R)Cha-Pro- and (R)Cha-Pic- often give rise to a cis-trans equilibrium with one conformer as the preponderant conformer (∼90%). In those cases only the $^1$H chemical shifts of the major rotamer is reported. Only in the cases where the signals of the minor rotamer are clearly resolved they are reported in the NMR documentation. The same criterium is valid for the NH-signals in CDCl$_3$, only in the cases where the signals are clearly resolved they are reported in the NMR-documentation. This implies that the number of protons reported for some of the intermediates are less than the number of protons expected from the chemical formula.

[0579] Thin-Layer Chromatography was carried out on commercial Merck Silicagel 60 F$_{254}$, coated glass or aluminium plates. Visualisation was by a combination of UV-light, followed by spraying with a solution prepared by mixing 372 ml of EtOH(95%), 13.8 ml of concentrated H$_2$SO$_4$, 4.2 ml of concentrated acetic acid and 10.2 ml of p-methoxy benzaldehyde or phosphomolybdc acid reagent (5-10 wct % in EtOH(95%)) and heating.

[0580] Flash chromatography was carried out on Merck Silica gel 60 (40-63 mm, 230-400 mesh) under pressure of air.

[0581] Reversed phase high-performance liquid chromatography (in the Examples referred to as RPLC) was performed on a Waters M-550 instrument equipped with three reverse phase columns (Eka-Nobel) having different dimensions for analytical (4.6 mm×250 mm), semipreparative (1×250 mm) and preparative (2×500 mm) chromatography detecting at 226 nm.

[0582] Freeze-drying was done on a Leybold-Heraeus, model Lyovac GT 2, apparatus.

[0583] Preparation of Starting Materials

Boc-(R)Pgl-OH

[0584] Prepared in the same way as described for Boc-(R)Cha-OH (vide infra) from H—(R)Pgl-OH.

Boc-(R)Cha-OH

[0585] To a solution of H—(R)Cha-OH, 21.55 g (125.8 mmol), in 130 ml 1 M NaOH and 65 ml THF was added 30 g (137.5 mmol) of (Boc)$_2$O and the mixture was stirred for 4.5 h at room temperature. The THF was evaporated and an additional 150 ml of water was added. The alkaline aqueous phase was washed twice with EtOAc, then acidified with 2 M KHSO$_4$ and extracted with 3×150 ml of EtOAc. The combined organic phase was washed with water, brine and dried (Na$_2$SO$_4$). Evaporation of the solvent afforded 30.9 g (90.5%) of the title compound as a white solid.

Boc-(R)Hop-OR

[0586] Prepared by the same procedure as described for Boc-(R)Cha-OH starting from H—(R)Hop-OH.

Boc-(R)Cha-Pic- 1H-NMR (300 MHz, CDCl$_3$): δ 1.45 (s, 9H), 2.00 (m, 1H), 2.22 (m, 1H), 2.75 (bt, 2H), 4.36 (bs, 1H), 5.05 (bs, 1H), 7.15-7.33 (m, 5H).

4-(tert-butoxy carbonylaminomethyl)pyridine

[0587] To a solution of 10.81 g (100 mmol) 4-aminomethyl pyridine in 100 ml THF was added 24 g (110 mmol) Boc$_2$O dissolved in 70 ml THF at 10$^\circ$ C. For 20 minutes. The solution was allowed to reach room temperature and stirred for 4 h (a precipitate was formed during the reaction and the slurry became red). The solvent was removed and the residue was dissolved in EtOAc and filtered through silica gel. Evaporation of the solvent gave the title compound as a red oil which crystallized on standing. The crude product was used without further purification.

Boc-(R)Pgl-OH

[0588] $^1$H-NMR (300 MHz, CDCl$_3$): δ 1.45 (s, 9H), 4.32 (d, 2H), 5.05 (bs, 1H(NH)), 7.2 (d, 2H), 8.55 (d, 2H).

4-aminomethyl-1-(N-benzylcarbonylamidino)-benzene (H-Pab(Z))

(i) 4-cyanobenzyl azide

[0589] A solution of 20.23 g (0.31 mol) sodium azide in 50 ml water was added to 49.15 g (251 mmol) 4-cyanobenzyl bromide in 200 ml DMF at ambient temperature. An exothermic reaction took place and after 1.5 h the reaction mixture was diluted with 200 ml toluene (caution: In order to avoid separation of potentially explosive azide compounds it is advisable to add the toluene to the reaction mixture before addition of the water) and 500 ml water. The aqueous phase was extracted with an additional 2×50 ml toluene. The combined organic extracts were washed with 2×50 ml water and brine and finally dried (MgSO$_4$) and filtered. The solution was used as such in the next step.

(ii) 4-amidino benzyl azide

[0592] Hydrogen chloride was bubbled into a mixture of 250 ml absolute ethanol and the solution from step (i) (approximately 200 ml) above at ~5$^\circ$ C. until saturation. Storage at 8$^\circ$ C. for 24 h and evaporation of most of the solvent followed by precipitation by addition of anhydrous ether gave white crystals which were isolated by filtration and dissolved in 1.81 l of alcoholic ammonia. After 48 h most of the solvent was removed and 200 ml 3.75 M NaOH solution was added whereupon 4-amidino benzyl azide precipitated as colourless crystals. The crystals were isolated by filtration. At this point the yield of 4-amidino benzyl azide was 22.5 g (total 51%).

[1288] Biology

[1289] Determination of Thrombin Clotting Time (TT):

[1290] Human thrombin (T 6769, Sigma Chem Co) in buffer solution, pH 7.4, 100 μl, and inhibitor solution, 100 μl, were incubated for one min. Pooled normal citrated human plasma, 100 μl, was then added and the clotting time measured in an automatic device (KC 10, Amelung).

[1291] The clotting time in seconds was plotted against the inhibitor concentration, and the IC50 TT was determined by interpolation.

[1292] IC50 TT is the concentration of inhibitor that doubles the thrombin clotting time for human plasma.

[1293] Determination of Activated Partial Thromboplastin Time (APTT)

[1294] APTT was determined in pooled normal human citrated plasma with the reagent PTT Automated 5 manufactured by Stago. The inhibitors were added to the plasma (10 μl inhibitor solution to 90 μl plasma) and APTT was determined in the mixture by use of the coagulation analyser KC10 (Amelung) according to the instructions of the reagent producer. The clotting time in seconds was plotted against the inhibitor concentration in plasma and the IC50 APTT was determined by interpolation.

[1295] IC50 APTT is defined as the concentration of inhibitor in plasma that doubled the Activated Partial Thromboplastin Time.

[1296] Determination of Thrombin Time Ex Vivo

[1297] The inhibition of thrombin after oral administration of the compounds were examined in conscious rats that two days prior to the experiment were equipped with a catheter for blood sampling from the carotid artery. On the experimental day blood samples were withdrawn at fixed times after the administration of the compound into plastic tubes containing 1 part sodium citrate solution (0.13 mol per L.) and 9 parts of blood. The tubes were centrifuged to obtain platelet-poor plasma. The plasma was used for determination of thrombin time as described below.

[1298] The citrated rat plasma, 100 μl, was diluted with a saline solution, 0.9%, 100 μl, and plasma coagulation was started by the addition of human thrombin (T 6769, Sigma Chem Co, USA) in a buffer solution, pH 7.4, 100 μl. The clotting time was measured in an automatic device (KC 10, Amelung, Germany).

[1299] Determination of the Inhibition Constant KI for Plasma Kallikrein

[1300] KI determinations were made with a chromogenic substrate method, and performed on a Cobas Bio centrifugal analyzer manufactured by Roche (Basel, Switzerland). Residual enzyme activity after incubation of human plasma kallikrein with various concentrations of test compound was determined at three different substrate concentrations, and measured as change in optical absorbance at 405 nm and 37° C.

[1301] Human plasma kallikrein (E.C.3.4.21.34, Chromogen AB, Mölndal, Sweden), 250 μl of 0.4 nkat/ml in buffer. (0.05 mol/L Tris·HCl, pH 7.4, 1.0 0.15 adjusted with NaCl) with bovine albumin 5 g/l (cat no 810033, ICI Biochemicals Ltd, High Wycombe, Bucks, GB), was incubated for 300 s with 80 μl of test compound solution in 0.15 mol/l NaCl containing albumin 10 g/l. An additional 10 μl of water was supplied in this step. Then 40 μl of kallikrein substrate (S-2302, Chromogen AB, 1.25, 2.0 or 4.0 mmol/l in water) was added together with another 20 μl of water, and the absorbance change monitored.

[1302] KI was evaluated from Dixon plots, i.e. diagrams of inhibitor concentration versus 1/(AA/min), where the data for the different substrate concentrations form straight lines which intercept at x=KI.
