(54) Title: APPARATUS FOR MAKING A MULTI-LAYER INJECTION BLOW MOLDED CONTAINER

(57) Abstract

Apparatus for making a rigid container by injection molding a parison having plural layers of polymers including interior and outer layers in an injection mold (20) having a core pin (10A, 10B). A blow mold (30A, 30B) is used to blow the parison to the final shape of the container. Control devices (100, 110, 115, 120) exercise control over each of the plural plasticators (82A, 82B, 82C) and rams (70A, 70B, 70C) for the plural polymers so as to produce uninterrupted layers extending throughout the walls of the parison and to insure that the interior layers are completely encapsulated within the outer layers.

APPARATUS FOR MAKING A MULTI-LAYER INJECTION BLOW MOLDED CONTAINER

Food product rigid containers generally must be impermeable to oxygen. Most common structural polymers for rigid food containers are permeable to oxygen which invades the food product causing degradation or spoilage. Those polymers which are sufficiently impermeable to oxygen generally are not suitable alone for rigid containers for foods because they do not possess adequate structural properties, are moisture sensitive, or are not approved for or are of questionable safety when used in contact with foods. Ethylene vinyl alcohol copolymer (EVOH) is a transparent extrusible material possessing high impermeability to oxygen when dry, many times less permeable than acrylonitrile copolymers, but is very moisture sensitive. The oxygen barrier properties of EVOH are markedly diminished in the presence of significant quantities of water. To be useful for food packaging, particularly where extended shelf life is required, EVOH must be kept dry as by total encapsulation within polymers which have good moisture barrier properties.

Many foods are processed in the container in a pressure cooker or retort. Retort conditions commonly are 250°F. at 30 psia steam pressure. A rigid container must survive retort conditions. It must not permanently distort during cooking or during cooling, and must not suffer an alteration of the desirable properties of its components. Polyolefins, particularly blends or copolymers of polypropylene and polyethylene, are well suited to manufacture of rigid containers and have adequate physical properties to survive retorting. Polyolefins are relatively poor oxygen barriers, but are relatively good moisture barriers. The use of polyolefins with a central core of an oxygen barrier polymer is a desired goal of the food packaging industry.

Nohara et al 3,882,259 discloses a three ply plastic bottle having a core of EVOH blended with Surlyn A brand ionomer resin and outer plies of polyethylene blended with
Surlyn A. The Surlyn A ionomer is added to both the EVOH and the polyethylene resin materials to improve adhesion between layers. The bottle is to be made by extrusion blow molding whereby the three layers are simultaneously extruded to produce a three ply tube. While still hot from extrusion, the tube is pinched together at the bottom to form a seal and inflated in a blow mold having the shape of the desired bottle.

Extrusion blow molding has four serious drawbacks when used to form multi-layer containers having a core ply of a moisture sensitive barrier material such as EVOH.

First, the pinch seal at the bottom leaves the core ply of EVOH exposed on the bottle exterior. Since EVOH and certain other barrier materials are adversely affected by moisture, exposure of the core ply at the container bottom renders the container susceptible to loss of barrier quality by intrusion of moisture. The risk that the container exterior will encounter damp conditions in storage or transport is high and the resulting loss of barrier quality will degrade or spoil the food. Further, retort conditions are such that moisture from the steam will intrude into the barrier layer through the exposed barrier at the bottom.

Second, extrusion blow molding necessarily produces scrap as a result of the pinch sealing procedure. Since the scrap contains materials from each of the three layers, reextrusion of the scrap is difficult and expensive.

Third, the pinch seal produces a bottom of non-uniform thickness and strength. The sealing takes place along a line between the abutting faces of the inner layer material. The seal line is bordered by regions of relatively thick material. When stretched during blow molding, the bottom varies in thickness in the vicinity of the pinch seal. Because of the thickness variation due to the pinch seal, the stiffness of the bottom is not uniform along all diameters. Consequently, the bottom does not evenly respond to expansion and contraction as the product changes in temperature. This lack of even
response causes unpredictable performance of the container when retorted.

Fourth, the pinch seal may create an interruption in the barrier layer. If the inside surface layer is interposed between the barrier layer at the seal, a line lacking barrier material will result. The area of the interruption may be great enough to allow sufficient oxygen to enter to be a problem.

Because of these disadvantages, extrusion blow molding cannot produce an entirely satisfactory three layer rigid container having a core barrier layer of a moisture sensitive polymer such as EVOH, particularly where the container is intended for retorting.

SUMMARY OF THE PRESENT INVENTION

The present invention is concerned with apparatus for making a plastic container by injection molding or by an injection blow molding technique which produces a container whose walls are multiple plies of different polymers. In particular, the container walls comprise inner and outer layers of structural polymers such as polyolefins or a blend of polyolefins on either side of a core layer of a polymer having oxygen barrier properties such as EVOH.

Injection blow molding is a process whereby a preform or parison is formed by injection molding in a cavity. The parison is transferred to a blow mold cavity and blown to the shape of the desired container. The parison can be retained on the core pin of the injection mold and transferred on the core pin to the blow molding cavity. The parison can be temperature conditioned before blow molding to achieve an optimum temperature or profile of temperatures. The core pin can be temperature controlled and the exterior of the parison can be temperature conditioned by contact with air or other fluid such that blow molding occurs at optimal conditions. Orientation can be achieved as the parison is stretched during blow molding. Injection blow molding produces no scrap and requires no pinch seal.
According to the present invention, polymer melts for the inside and outside surface layers and the core layers of the container walls are substantially simultaneously injected into a parison mold cavity through an injection nozzle having separate passages for each polymer melt arranged to lead coaxial annular nozzle orifices surrounding the central orifice. Additional layers or layers interposed between the surface and core layers can also be injected simultaneously to produce a container wall having four or more layers.

The initiation, rate, and termination of flow for each layer are independently and continuously controlled to provide control over the thickness of each layer and to insure that the core layer or layers are totally encapsulated between the surface layers. The injection molded parison is transferred on the core pin to a blow mold cavity having the shape of the container and is then blow molded into the finished container. Temperature conditioning of the parison just prior to blowing can result in biaxial orientation of the various polymers to achieve desirable improvements in physical properties such as impermeability, clarity, tensile strength, impact strength, and resistance to creep. The resulting product has a barrier layer of layers which extend without interruption throughout the container, yet are completely encapsulated within the material of the inside and outside surface layers. Since the barrier layer is protected from moisture by the moisture barrier properties of the surface layers, the oxygen barrier quality is preserved.

DESCRIPTION OF A PREFERRED EMBODIMENT

The machine of the present invention injection molds a multi-layer parison from a plurality of polymers, each separately plasticated and fed to separate injection rams. The rams each force a shot of polymer to appropriate nozzle passages which lead to the entrance to the injection mold cavity. Conditions are controlled to advance the several polymer melts substantially simultaneously in the die cavity under non-turbulent flow conditions to preserve the polymers as discrete layers in the parison. The
following detailed description explains how the foregoing is accomplished.

Figure 1 shows a portion of the injection blow molding machine (IBM) of the present invention. Two core pins 10A, 10B are mounted on a transversely moveable plate 40 on the axially moveable platen 42 of the machine. Core pin 10A is positioned in an injection mold 20 while core pin 10B is positioned in a blow mold 30B. When plate 40 is traversed to the left, core pin 10A will be in blow mold 30A and core pin 10B will be in the injection mold 20. A parison is removed from the mold by axial retreat of the moveable platen 42 and the plate 40 with core pins 10 is traversed either left or right to the available blow mold. Figure 1 shows blow mold 30A ready to receive the parison and shows blow mold 30B containing a parison 60B. Parison 60B is inflated with air to assume the shape of blow molding cavity 30B while parison 60A is being injected in cavity 20. The blow molds open as the platen retreats to eject the finished container. The plate 40 shuttles back and forth each cycle so that a container is blown simultaneously each time a parison is injected.

Figure 2 shows the general layout of the injection blow molding machine and indicates the control means. Plasticators 82A, 82B, 82C feed three rams 70A, 70B, 70C for three polymer melts which are fed to a manifold block 75 which contains separate passages leading to a multi-passage nozzle 50 for the injection mold 20. The platen 42 is moved axially of the mold by a hydraulic press 44.

Control circuitry means for the press and blowing cycles are indicated at press control block 110. A microprocessor 100 is programmed to control the servo hydraulics 120 which control the individual injection rams and to command the press control block 110.

Figure 3 shows one of the plural plasticators 82B for melting and supplying molten polymer B to an injection
ram 70B. The plasticator 82B is a conventional reciprocating screw device which forces molten polymer into the cylinder 71B of the ram when manifold valve 84B is closed and manifold valve 85B is opened and the ram is retreated to the left by hydraulic actuator 72B. When the ram cylinder 71B is charged with molten resin, valve 85B is closed. Upon a control signal from the microprocessor 100, valve 84B is opened and the servo control 120 for the ram causes the ram to advance to the right, according to a displacement-time schedule stored in the microprocessor program. A displacement transducer 76 provides an analog signal proportional to ram displacement to complete a feed-back loop for the servo 120. Polymer B forced according to the program flows past valve 84B through the manifold passages to the injection nozzle, through the nozzle passages and into the injection mold cavity where polymer B becomes the outside layer of a parison 60.

Figure 4 shows schematically the servo loop where the control signal from the microprocessor 100 (shown as voltage as a function of time) and a position signal from the displacement transducer 76 are algebraically combined in an amplifier 78 and the resulting signal is used to control the hydraulic servo 120 for the hydraulic actuator 72. A typical ram position control signal is shown in Figure 5. Since displacement is measured by transducer 76, the plot is in voltage as a function of time.

Figure 6 is a flow chart of the system used to control the machine. The injection blow molding machine is indicated as IBM on the chart. Upon initiation of the cycle, the program checks positions of valves, rams, etc. and if all are proper, recharges the ram cylinders 71 from the plasticators 82. The IBM control circuit 110 provides an "inject" signal to the microprocessor 100. Injection is carried out according to the ram displacement-time schedule of the microprocessor and is terminated at the end of the schedule. An "injection complete" signal is sent to the IBM. The control 110 then causes the IBM to traverse to place the parison in the blow mold and to
proceed with the blow molding phase. The machine continues to cycle through this sequence. Keyboard 115 may be used to change the displacement-time schedule or to shut down the machine.

Figure 7 is a plot of ram displacement as a function of time for three rams. The positions of the rams are measured as the voltage analog output of the transducers 76 for each ram. The polymer for the inside surface layer is "A"; that for the core layer "C"; and that for the outside surface layer is "B". In this figure an upward slope indicates a forward motion of the ram to deliver polymer, a horizontal slope indicates a stopped ram, and a downward slope indicates a retreat of the ram. The significance of Figure 7 is perhaps better understood by reference to Figures 8-15, which show the flow of the polymers at the exit of the nozzle 50 and the entrance 52 of the injection mold cavity 20 at the rounded bottom of the parison. Figures 8-15 are taken at different times in the cycle and those times are keyed to Figure 7.

Figure 8 represents the conditions at the start of a cycle at time 0. The cavity 20 is empty. The entrance 52 of the cavity 20 initially contains only the polymers A and B for the inside and outside surface layers. The rams for polymers A and B begin to advance to force those polymers into the cavity. At about 100 milliseconds into the cycle the ram for the core layer, polymer C, begins to advance. Figure 9 shows that polymer C has joined the flow stream in the entrance and polymer C is about to enter the cavity. Figure 10, taken at about 520 milliseconds, shows the flow of the three polymers as the cavity continues to be filled. All three polymer layers must extend throughout the entire length of the parison. Since the flow in the mold cavity is laminar, the velocity in the middle of the stream is higher than the velocities at the cavity walls. Therefore, initiation of flow of polymer C is retarded enough (e.g., about 100 milliseconds) so that polymer C will reach the far end of the cavity just as the slower moving surface layers
(A and B) reach the end. In this way, the far end of the parison, that which becomes the mouth end of the container, will have all layers present in their proper positions.

At about 1000 milliseconds into the injection cycle, the ram for polymer A (the inside surface layer) is stopped and the ram for polymer C (the core layer) can be accelerated slightly to achieve the desired thickness of material in the bottom of the container. Polymer A is necked down in the entrance 52 is shown in Figure 11 until it effectively is severed as shown in Figure 12. At 110 milliseconds the ram for polymer C is stopped and the ram for polymer A is restarted. Figures 13 and 14 show polymer A advancing to pinch off polymer C in the entrance, thereby pushing the last of polymer C into the cavity 20 with polymer A to bury or encapsulate to isolate polymer C from exposure at the surface of the parison. Figure 15 shows polymer A knit to polymer B at the entrance to complete the encapsulation of polymer C and to return to the conditions at the start as shown in Figure 8. At the time of Figure 15 (1300 milliseconds) all three rams are retreated to depressurize the cavity to prevent expansion of the parison when the cavity is opened and to depressurize the polymers remaining in the nozzle and entrance to prevent exudation from the nozzle while the cavity is open. This exudation leads to premature flow of polymers into the cavity during the next cycle which can lead to smearing of polymer C on the surfaces of the container.

1500 milliseconds marks the end of the injection phase of the machine cycle for this example. Subsequent to the end of the injection phase of the cycle, manifold valves 84, 85 are actuated and the ram cylinders 71 are recharged with their polymers by the plasticators 82. The injection mold is opened by retracting the hydraulic press 44 to withdraw the core pin 10 from the cavity 20. The parison just formed is transferred to one of the blow mold cavities 30A, 30B and the container which was blow
molded simultaneously with the injection cycle is ejected from the blow mold in which it was finished.

Figure 16 shows a nozzle 50 appropriate for injection of a parison having a three layer wall. Polymer B, which forms the outside surface layer, is delivered by the ram 70B to an annular distribution channel 54B which distributes the polymer circumferentially of the nozzle structure. Polymer B advances along a conical passage 56B to an annular orifice 58B at the exit of the nozzle which leads to the injection cavity. Similarly, polymer C, which forms the core layer, is delivered by ram 70C to annular distribution channel 54C and thence along conical passage 56C to annular orifice 58C. Polymer A, which forms the inside surface layer, is delivered by the ram 70A to a passage 56A which exits at the center of the concentric flows issuing from orifices 58B and 58C. A nozzle shut off valve 59 can be moved axially to arrest flow of polymer A.

Figures 17 and 18 compare the parison 60 as injection molded with the finished container. The neck portion 62 remains virtually unchanged during blow molding. The parison is held by the chilled neck portion while the hot and soft parison is blown. Thus, the neck 62 including the flange 64 is essentially formed in the injection mold. The remainder of the parison walls are thinned as the parison is stretched during blow molding.

Figure 18 shows that the core layer C extends throughout the flange 64, but does not penetrate the flange edge. This is accomplished in large part by selection of the delay time in starting the ram for the core polymer. The flange 64 will be employed in a double seam seal when a metal end is crimped, by well known techniques, onto the container mouth to close the filled container. Since the flange represents a significant area, it is important that the core layer extend well into the flange. The programmed flows of the various polymers also ensure that the core layer is not exposed at the sprue mark at the central exterior of the container.
Figure 19 is an enlargement of the container wall within the circle of Figure 18. Layer A is the inside surface layer formed from polymer A in the foregoing description. Layer B is the outside surface layer, formed from polymer B. Layer C is the core or barrier layer formed from polymer C. The thinnest layer is the relatively expensive barrier polymer C. The relative thickness of the three layers is controlled by controlling the relative flow rates of the three polymers by microprocessor control of the displacement rates of the rams. A preferred wall structure is a layer of a blend of high density polyethylene and polypropylene on each face of a core barrier layer of ethylene vinyl alcohol copolymer (EVOH).

Figure 20 shows how the oxygen barrier quality of the EVOH layer is thin, only a small quantity of water will cause a large increase in oxygen permeability. For this reason, the EVOH layer must adequately be protected against the intrusion of moisture.

Polyolefins do not adhere well to EVOH. Adhesion can be improved by adding adhesion promoters to the polyolefin, the EVOH or both. Another approach is to provide an intermediate layer of an adherent polymeric material which adheres to the polyolefin and the EVOH. Such materials include modified polyolefins sold under the name Plexar by the Chemplex Company of Rolling Meadows, Illinois. These comprise a blend of a polyolefin and a graft copolymer of high density polyethylene and an unsaturated fused ring carboxylic acid anhydride. The polyolefin component of the blend can be polyethylene or preferably is an olefin copolymer such as ethylene vinyl acetate. Schroeder application S.N. filed 28 December 1978 teaches the use of these materials to bond to EVOH. The materials themselves are disclosed in U.S. patents 4,087,587 and 4,087,588. We have found these modified polyolefins to be suitable as interlayers to improve adhesion between the polyolefin surface layers and the EVOH core layer.

Another suitable material for use as an interlayer to
improve adhesion between the EVOH polyolefins are maleic
anhydride grafted polyolefins sold under the name Admer by
Mitsui Petrochemical Industries of Tokyo, Japan.

The use of interlayers on each side of the EVOH oxygen
barrier layer results in a five layer container. To produce
such a container, the three passage nozzle of Figure 16 is
replaced with a five passage nozzle of similar construction.
Where the inside and outside surface layers are of the same
polymer one ram can be used for both those layers. The flow
from that ram is divided and proportioned with part
supplying the central axial passageway to form the inside
surface layer and the balance supplying the outermost nozzle
annular orifice. The two additional nozzle orifices are
located just inside and just outside the nozzle orifice for
the EVOH barrier layer. The two additional annular nozzle
orifices can be supplied with the interlayer polymer from a
single ram, the flow being divided and proportioned. Thus, a
three ram machine can produce a five layer parison. Greater
control can be exercised over the polymer flows by using a
machine with an independently controllable ram for each
layer. A nozzle shut off valve can be employed to selec-
tively control the polymer flows. The three layers of
interlayer polymer and the barrier polymer can be treated as
a single core layer. A five layer wall is shown in Figure
21 wherein layers A and B are the inside surface layers of
polyolefin, layer C is the barrier layer of EVOH, and two
layers D are the interlayer material.

EXAMPLE I

Five layer containers have a capacity of about 5 1/2
ounces, of 202 x 307 size, weighing about 11g were made
using a five orifice nozzle on a three ram machine. The
inside and outside surface layers were polypropylene-
polyethylene block copolymer (Hercules Profax 7631). The
adhesive interlayers were ethylene vinyl acetate copolymer
blended with a graft copolymer of high density
polyethylene and a fused ring carboxylic acid anhydride (Plexar 1615-2). The oxygen barrier was EVOH (Kuraray EVAL EP-F, available from Kuraray Co. Ltd., Osaka, Japan). The layers were well adhered. The barrier extended to the flange lip and was completely encapsulated.

EXAMPLE II

Five layer containers similar to those of Example I were made wherein the inside and outside surface layers were polypropylene (EXXON E612); the interlayer material was Plexar III, a blend of ethylene vinyl acetate copolymer and a graft copolymer; and the barrier was EVAL EP-F. The layers were well adhered. The barrier layer extended to the lip of the flange and was completely encapsulated.

EXAMPLE III

Five layer containers similar to those of Example I were made wherein the inside and outside surface layers were a 50-50 blend of polypropylene (EXXON E612) and high density polyethylene (Chemplex 5701); the interlayer material was Plexar III; and the barrier layer was EVAL EP-F. The layers were well adhered. The barrier layer extended to the lip of the flange and was completely encapsulated.

EXAMPLE IV

Five layer containers similar to those of Example I were made wherein the inside and outside surface layers were a copolymer of propylene and ethylene (Hercules Profax 7631); the interlayer material was maleic anhydride grafted polyolefin (Mitsui Admer QB 530); and the barrier layer was EVAL EP-F. The layers were well adhered. The barrier layer extended to the lip of the flange and was completely encapsulated.
In the making of the containers of Examples I-IV the injection schedule began feeding the inside and outside surface layer polymer then the polymer for the adhesive interlayer was started and substantially simultaneously the barrier layer polymer was started. The flows of the adhesive interlayer polymer and the barrier layer polymer were terminated before the outside surface layer polymer flow was terminated.
CLAIMS

1. Apparatus for making a multi-layer rigid article comprising:
   A) an injection mold and a core pin which together define a cavity for molding a parison, the cavity having an entrance at the bottom of the parison,
      1) means for independently commencing the flow of a first polymer stream to become the inside surface layer of the parison and the flow of a second polymer stream to become the outside surface layer of the parison, and the flow of a third polymer stream between the first and second polymer streams,
      2) means for independently controlling the rates of flow of the polymer streams,
      3) means for independently terminating the flows of the polymer streams,
   B) means for transferring the injection molded parison to a blow molding cavity having the configuration of the article,
   C) means for inflating the parison in the blow molding cavity to form the article

2. The apparatus of claim 1 including means for introducing a fourth polymer stream between the third and first polymer streams and means for introducing a fifth polymer stream between the third and second polymer streams, and means for controlling and for terminating the flows of the fourth and fifth polymer streams.

3. Apparatus for making a multi-layer rigid container comprising:
   A) an injection mold and a core pin which together define a cavity for molding a parison, the cavity having an entrance for polymer at the closed end of the parison,
      1) means for establishing in the entrance a flow of polymer comprising a central stream of a first
polymer surrounded by an annular stream of a second polymer,

2) means for establishing an annular stream of a third polymer between the first and second polymer streams,

3) means for independently controlling the flow of the three polymer streams until the cavity is nearly filled,

4) means for independently terminating the flow of the polymer streams,

B) means for transferring the parison to a blow mold cavity,

C) means for inflating the parison in the blow mold cavity to blow mold the parison into the finished container.

4. The apparatus for making a multi-layer injection molded article comprising:

1) means for independently commencing the flow of a first polymer stream to become one surface layer of the article, the flow of a second polymer stream to become the other surface layer of the article, and the flow of a third polymer stream between the first and second polymer streams,

2) means for independently controlling the flow of the polymer streams, and

3) means for independently terminating the flow of the polymer streams.

5. Apparatus for forming a multi-layer plastic parison for an injection blow molded article comprising:

1) means for commencing the injection of a first inside surface layer,

2) means for commencing the injection of a second outside surface layer,

3) means for commencing the injection of a third core layer,

4) means for independently terminating the injection of the first, second and third layers.
6. Apparatus for injection blow molding a multi-layer rigid container comprising:
   an injection mold for a parison,
   two core pins mounted on a plate which transverses to register either pin with the injection mold,
   two blow molds for blow molding the parison into the container, the blow molds being located to register one blow mold with one core pin when the other core pin is registered with the injection mold,
   an injection nozzle in communication with the injection mold at the bottom of the parison, the nozzle having a plurality of concentric orifices,
   a plurality of polymer injection means associated with the nozzle orifices, and
   control means to independently control the polymer flows as a function of time.

7. The apparatus of claim 6 wherein the plurality of injection means comprises a plurality of injection rams and a plurality of plasticators for supplying molten polymer to the injection rams, and wherein the control means control the displacement of the injection rams.

8. Apparatus for injection molding a multi-layer container comprising:
   at least three plasticators for independently melting polymers for the different layers,
   at least three servo controlled hydraulically actuated injection rams associated with the plasticators,
   an injection nozzle having at least three independent polymer orifices, each associated with a ram,
   a linear transducer for each ram for producing an electrical signal related to the linear displacement of the ram,
   means to generate a time-displacement schedule signal for each ram,
   means to control the servo hydraulic actuator for
each ram in accordance with the algebraic sum of the two signals.

| V. OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE |

This international search report has not been established in respect of certain claims under Article 17(3)(a) for the following reasons:

1. Claim numbers -------- because they relate to subject matter not required to be searched by this Authority, namely:

2. Claim numbers -------- because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

| VI. OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING |

This International Searching Authority found multiple inventions in this international application as follows:

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.

2. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:

Remark on Protest:
- The additional search fees were accompanied by applicant's protest.
- No protest accompanied the payment of additional search fees.
