INHIBITORS OF CYSTEINE PROTEASE

Field of the Invention

This invention relates to novel protease inhibitors, particularly inhibitors of cysteine and serine proteases, more particularly compounds which inhibit cysteine proteases, even more particularly compounds which inhibit cysteine proteases of the papain superfamily, yet more particularly compounds which inhibit cysteine proteases of the cathepsin family, most particularly compounds which inhibit cathepsin K. Such compounds are particularly useful for treating diseases in which cysteine proteases are implicated, especially diseases of excessive bone or cartilage loss, e.g., osteoporosis, periodontitis, and arthritis.

Background of the Invention

Cathepsin K has been variously denoted as cathepsin O, cathepsin X or cathepsin O2 in the literature. The designation cathepsin K is considered to be the more appropriate one (name assigned by Nomenclature Committee of the International Union of Biochemistry and Molecular Biology).

Cathepsins of the papain superfamily of cysteine proteases function in the normal physiological process of protein degradation in animals, including humans, e.g., in the degradation of connective tissue. However, elevated levels of these enzymes in the body can result in pathological conditions leading to disease. Thus, cathepsins have been implicated in various disease states, including but not limited to, infections by pneumocystis carinii, trypansoma cruzi, trypansoma brucei brucei, and Crithidia fusculata; as well as in schistosomiasis malaria, tumor metastasis, metachromatic leukodystrophy, muscular dystrophy, amyotrophy, and the like. See International Publication Number WO 94/04172, published on March 3, 1994, and references cited therein. See also European Patent Application EP 0 603 873 A1, and references cited therein. Two bacterial cysteine

Cathepsin K is believed to play a causative role in diseases of excessive bone or cartilage loss. Bone is composed of a protein matrix in which spindle- or plate-shaped crystals of hydroxyapatite are incorporated. Type I Collagen represents the major structural protein of bone comprising approximately 90% of the structural protein. The remaining 10% of matrix is composed of a number of non-collagenous proteins, including osteocalcin, proteoglycans, osteopontin, osteonectin, thrombospondin, fibronectin, and bone sialoprotein. Skeletal bone undergoes remodeling at discrete foci throughout life. These foci, or remodeling units, undergo a cycle consisting of a bone resorption phase followed by a phase of bone replacement.

Bone resorption is carried out by osteoclasts, which are multinuclear cells of hematopoietic lineage. The osteoclasts adhere to the bone surface and form a tight sealing zone, followed by extensive membrane ruffling on their apical (i.e., resorbing) surface. This creates an enclosed extracellular compartment on the bone surface that is acidified by proton pumps in the ruffled membrane, and into which the osteoclast secretes proteolytic enzymes. The low pH of the compartment dissolves hydroxyapatite crystals at the bone surface, while the proteolytic enzymes digest the protein matrix. In this way, a resorption lacuna, or pit, is formed. At the end of this phase of the cycle, osteoblasts lay down a new protein matrix that is subsequently mineralized. In several disease states, such as osteoporosis and Paget's disease, the normal balance between bone resorption and formation is disrupted, and there is a net loss of bone at each cycle. Ultimately, this leads to weakening of the bone and may result in increased fracture risk with minimal trauma.

The abundant selective expression of cathepsin K in osteoclasts strongly suggests that this enzyme is essential for bone resorption. Thus, selective inhibition of cathepsin K may provide an effective treatment for diseases of excessive bone loss, including, but not limited to, osteoporosis, gingival diseases such as gingivitis and periodontitis, Paget's disease, hypercalcemia of malignancy, and metabolic bone disease. Cathepsin K levels have also been demonstrated to be elevated in chondroclasts of osteoarthritic synovium. Thus, selective inhibition of cathepsin K may also be useful for treating diseases of excessive cartilage or matrix degradation, including, but not limited to, osteoarthritis and rheumatoid arthritis. Metastatic neoplastic cells also typically express high levels of proteolytic enzymes that degrade the surrounding matrix. Thus, selective inhibition of cathepsin K may also be useful for treating certain neoplastic diseases.

It now has been discovered that a novel class of compounds are protease inhibitors, most particularly inhibitors of cathepsin K, and these compounds are useful for treating
diseases in which inhibition of bone resorption is indicated, such as osteoporosis and periodontal disease.

Compounds of the general formula (I) wherein n is 0 or 1, R¹ and R² are amides and R" is hydrogen are prepared as outlined in Scheme 1. Treatment of the commercially available 3-pyrroline (1-Scheme-1; n = 0) or 1,2,3,6-tetrahydropyridine (1-Scheme-1; n = 1) under conditions which are known in the art for nitrogen protection, such as di-tert-butyl dicarbonate, gave 2-Scheme-1 (n = 0, 1). 2-Scheme-1 is epoxidized by standard conditions, such as meta-chloroperoxybenzoic acid, to provide the epoxide 3-Scheme-1 (n = 0, 1). The epoxide 3-Scheme-1 may be opened with sodium azide in a protic solvent, such as methanol and water, at an elevated temperature to give the azido alcohol 4-Scheme-1. The azide 4-Scheme-1 may be reduced to the amine 5-scheme-1 by methods that are common to the art, such as hydrogen with palladium on carbon as a catalyst, in a protic solvent, such as methanol or ethanol. The amine 5-Scheme-1 is acylated under standard conditions with EDC, HOBT and a carboxylic acid in an aprotic solvent, such as dichloromethane or DMF, to give 6-scheme-1. The amine 5-Scheme-1 may also be acylated with an acid chloride in the presence of an organic base such as triethylamine or N-methyl morpholine in an aprotic solvent such as dichloromethane to give the amide derivative 6-Scheme-1. The amine 5-Scheme-1 may also be sulfonylated to give the sulphonamide via methods that are known in the art such as treatment with a sulphonyl chloride, in the presence of an organic base, such as N-methylmorpholine, in an aprotic solvent such as dichloromethane.

Removal of the protecting group of 6-Scheme-1 may be accomplished by treatment with a strong acid, such as anhydrous hydrochloric acid or trifluoroacetic acid, in an anhydrous aprotic solvent, such as ethyl acetate or dichloromethane, to give 7-Scheme-1. The amine or amine salt of 7-Scheme-1 may be acylated under standard conditions, such as EDC, HOBT and a carboxylic acid or with an acid chloride, to give amide derivatives 8-Scheme-1 (n = 0, 1). The amine 7-Scheme-1 may also be alkylated by treatment with an aldehyde in an aprotic solvent, such as dichloromethane, followed by reduction with sodium cyanoborohydride or sodium triacetoxyborohydride. Alternatively, the amine 7-Scheme-1 may also be converted to the carbamate by treatment with a chloroformate in the presence of base, such as triethylamine or pyridine. The amine 7-Scheme-1 may also be converted to the sulphonamide by treatment with a sulphonyl chloride in the presence of a base. The alcohol derivatives 8-Scheme-1 may be oxidized to the ketone 9-Scheme-1 under standard conditions such as chromium trioxide in acetic acid, in a solvent, such as acetone. These alcohols may also be oxidised with methylsulfoxide and oxalyl chloride in an aprotic solvent, such as dichloromethane at -78°C, followed by treatment with an organic base, such as triethylamine, and warming to room temperature. Alternatively, the alcohols may be oxidised with pyridine sulphur trioxide complex in methylsulphoxide with an organic base, such as triethylamine.
Compounds of the formula (I) wherein \( n \) is 1, \( R^1 \) and \( R^2 \) are amides and \( R'' \) is hydrogen may also be prepared as detailed in Scheme 2. Coupling of 1,2,3,6-tetrahydropyridine with a carboxylic acid in the presence of EDC and HOBT or with an acid chloride provides the amide 1-Scheme-2. Epoxidation of 1-Scheme-2 with m-chloroperoxybenzoic acid yields the epoxide 2-Scheme-2 which is opened with sodium azide in the presence of ammonium chloride to provide the azido alcohol 3-Scheme-2. The azide is then reduced under standard conditions which are known in the art, such as 1,3-propanedithiol with triethylamine, in a protic solvent, such as methanol, to provide the amino alcohol 4-Scheme-2. Coupling of the amine 4-Scheme-2 with a carboxylic acid in the presence of EDC and HOBT provides 5-Scheme-2 which is oxidised by methods which are known in the art, such as DMSO, oxaly chlorid and triethylamine at low temperature, to yield the ketone 6-Scheme-2.
Compounds of the formula (I) wherein n is 1, R\textsuperscript{1} is amide, R\textsuperscript{2} is alkyl, may be synthesised as detailed in Scheme 3. Acylation of the amino alcohol \textit{L-}\textit{Scheme-3} with a chloroformate, such as benzyl chloroformate, in the presence of pyridine or triethylamine in an aprotic solvent, such as dichloromethane, provides \textit{2-Scheme-3}. Removal of the nitrogen protecting group from the secondary nitrogen by methods which are known in the art provides the amine \textit{3-Scheme-3}. This amine may be alkylated by treatment with an aldehyde followed by treatment with a reducing agent, such as sodium...
cyanoborohydride or sodium triacetaoxyborohydride, to yield 4-Scheme-3. Removal of the benzylloxycarbonyl protecting group via methods that are known in the art provides the amine 5-Scheme-3. This amine may be coupled with an acid in the presence of EDC and HOBT to provide the amide 5-Scheme-4. Oxidation of 5-Scheme-4 via methods that are known in the art, such as pyridine sulphur trioxide complex, provides the ketone 7-Scheme-3.

The epoxide 3-Scheme-4 may be opened with sodium azide in a protic solvent, such as methanol and water, at an elevated temperature to give the azido alcohol 4-Scheme-4. The azide 4-Scheme-4 may be reduced to the amine 5-Scheme-4 by methods that are common to the art, such as 1,3-propanedithiol with triethylamine, in a protic solvent, such as methanol. The amine 5-Scheme-4 is acylated under standard conditions with EDC, HOBT and a carboxylic acid in an aprotic solvent, such as dichloromethane or DMF, to give 6-Scheme-4. The amine 5-Scheme-4 may also be acylated with an acid chloride in the presence of an organic base, such as triethylamine or N-methyl morpholine, in an aprotic solvent, such as dichloromethane, to give the amide derivative 6-Scheme-4. Removal of the protecting group of 6-Scheme-4 is accomplished by methods known in the art, such as treatment with 10% palladium on carbon under hydrogen, to give 7-Scheme-4 compounds. The amine 7-Scheme-4 may be alkylated by treatment with an aldehyde in an aprotic solvent, such as dichloromethane, followed by reduction with sodium cyanoborohydride or sodium triacetoxyborohydride. Alternatively, the amine 7-Scheme-4 may be acylated under standard conditions such as EDC, HOBT and a carboxylic acid or with an acid chloride, as described previously, to give amide derivatives of 8-Scheme-4 (n = 0,1). The tert-butoxycarbonyl protecting group of 8-Scheme-4 may be removed by methods that are known in the art, such as treatment with hydrogen chloride or trifluoroacetic acid, in an aprotic solvent, such as dichloromethane or ethyl acetate. The amine salt may be coupled with an acid or acid chloride to give amides such as 10-Scheme-4. The starting materials used herein are commercially available amino acids or are prepared by routine methods well known to those of ordinary skill in the art and can be found in standard reference books, such as the COMPRENDIUM OF ORGANIC SYNTHETIC METHODS, Vol. I-VI (published by Wiley-Interscience).

Synthetic methods to prepare the compounds of this invention frequently employ protective groups to mask a reactive functionality or minimize unwanted side reactions. Such protective groups are described generally in Green, T.W., PROTECTIVE GROUPS IN ORGANIC SYNTHESIS, John Wiley & Sons, New York (1981). The term "amino protecting groups" generally refers to the Boc, acetyl, benzoyl, Fmoc and Cbz groups and derivatives thereof as known to the art. Methods for protection and deprotection, and replacement of an amino protecting group with another moiety are well known.

Acid addition salts of the compounds of formula (I) are prepared in a standard manner in a suitable solvent from the parent compound and an excess of an acid, such as hydrochloric, hydrobromic, hydrofluoric, sulfuric, phosphoric, acetic, trifluoroacetic, maleic, succinic or methanesulfonic. Certain of the compounds form inner salts or zwitterions which may be acceptable. Cationic salts are prepared by treating the parent compound with an excess of an alkaline reagent, such as a hydroxide, carbonate or alkoxyde, containing the appropriate cation; or with an appropriate organic amine. Cations such as \( \text{Li}^+, \text{Na}^+, \text{K}^+, \text{Ca}^{++}, \text{Mg}^{++} \) and \( \text{NH}_4^+ \) are specific examples of cations present in
pharmaceutically acceptable salts. Halides, sulfate, phosphate, alkanoates (such as acetate and trifluoroacetate), benzoates, and sulfonates (such as mesylate) are examples of anions present in pharmaceutically acceptable salts.

This invention also provides a pharmaceutical composition which comprises a compound according to formula (I) and a pharmaceutically acceptable carrier, diluent or excipient. Accordingly, the compounds of formula (I) may be used in the manufacture of a medicament. Pharmaceutical compositions of the compounds of formula (I) prepared as hereinbefore described may be formulated as solutions or lyophilized powders for parenteral administration. Powders may be reconstituted by addition of a suitable diluent or other pharmaceutically acceptable carrier prior to use. The liquid formulation may be a buffered, isotonic, aqueous solution. Examples of suitable diluents are normal isotonic saline solution, standard 5% dextrose in water or buffered sodium or ammonium acetate solution. Such formulation is especially suitable for parenteral administration, but may also be used for oral administration or contained in a metered dose inhaler or nebulizer for insufflation. It may be desirable to add excipients such as polyvinylpyrrolidone, gelatin, hydroxy cellulose, acacia, polyethylene glycol, mannitol, sodium chloride or sodium citrate.

Alternately, these compounds may be encapsulated, tableted or prepared in an emulsion or syrup for oral administration. Pharmaceutically acceptable solid or liquid carriers may be added to enhance or stabilize the composition, or to facilitate preparation of the composition. Solid carriers include starch, lactose, calcium sulfate dihydrate, terra alba, magnesium stearate or stearic acid, talc, pectin, acacia, agar or gelatin. Liquid carriers include syrup, peanut oil, olive oil, saline and water. The carrier may also include a sustained release material such as glyceryl monostearate or glyceryl distearate, alone or with a wax. The amount of solid carrier varies but, preferably, will be between about 20 mg to about 1 g per dosage unit. The pharmaceutical preparations are made following the conventional techniques of pharmacy involving milling, mixing, granulating, and compressing, when necessary, for tablet forms; or milling, mixing and filling for hard gelatin capsule forms. When a liquid carrier is used, the preparation will be in the form of a syrup, elixir, emulsion or an aqueous or non-aqueous suspension. Such a liquid formulation may be administered directly p.o. or filled into a soft gelatin capsule.

For rectal administration, the compounds of this invention may also be combined with excipients such as cocoa butter, glycerin, gelatin or polyethylene glycols and molded into a suppository.

The compounds of formula (I) are useful as protease inhibitors, particularly as inhibitors of cysteine and serine proteases, more particularly as inhibitors of cysteine proteases, even more particularly as inhibitors of cysteine proteases of the papain

superfamily, yet more particularly as inhibitors of cysteine proteases of the cathepsin family, most particularly as inhibitors of cathepsin K. The present invention also provides useful compositions and formulations of said compounds, including pharmaceutical compositions and formulations of said compounds.

The present compounds are useful for treating diseases in which cysteine proteases are implicated, including infections by pneumocystis carinii, trypanosoma cruzi, trypanosoma brucei, and crithidia fasiculata; as well as in schistosomiasis, malaria, tumor metastasis, metachromatic leukodystrophy, muscular dystrophy, amyrophy; and especially diseases in which cathepsin K is implicated, most particularly diseases of excessive bone or cartilage loss, including osteoporosis, gingival disease including gingivitis and periodontitis, arthritis, more specifically, osteoarthritis and rheumatoid arthritis, Paget's disease, hypercalcemia of malignancy, and metabolic bone disease.

Metastatic neoplastic cells also typically express high levels of proteolytic enzymes that degrade the surrounding matrix, and certain tumors and metastatic neoplasias may be effectively treated with the compounds of this invention.

The present invention also provides methods of treatment of diseases caused by pathological levels of proteases, particularly cysteine and serine proteases, more particularly cysteine proteases, even more particularly as inhibitors of cysteine proteases of the papain superfamily, yet more particularly cysteine proteases of the cathepsin family, which methods comprise administering to an animal, particularly a mammal, most particularly a human in need thereof a compound of the present invention. The present invention especially provides methods of treatment of diseases caused by pathological levels of cathepsin K, which methods comprise administering to an animal, particularly a mammal, most particularly a human in need thereof an inhibitor of cathepsin K, including a compound of the present invention. The present invention particularly provides methods for treating diseases in which cysteine proteases are implicated, including infections by pneumocystis carinii, trypanosoma cruzi, trypanosoma brucei, and crithidia fasiculata; as well as in schistosomiasis, malaria, tumor metastasis, metachromatic leukodystrophy, muscular dystrophy, amyrophy, and especially diseases in which cathepsin K is implicated, most particularly diseases of excessive bone or cartilage loss, including osteoporosis, gingival disease including gingivitis and periodontitis, arthritis, more specifically, osteoarthritis and rheumatoid arthritis, Paget's disease, hypercalcemia of malignancy, and metabolic bone disease.

This invention further provides a method for treating osteoporosis or inhibiting bone loss which comprises internal administration to a patient of an effective amount of a compound of formula (I), alone or in combination with other inhibitors of bone resorption, such as bisphosphonates (i.e., alendronate), hormone replacement therapy, anti-estrogens.
or calcitonin. In addition, treatment with a compound of this invention and an anabolic agent, such as bone morphogenic protein, iproflavone, may be used to prevent bone loss or to increase bone mass.

For acute therapy, parenteral administration of a compound of formula (I) is preferred. An intravenous infusion of the compound in 5% dextrose in water or normal saline, or a similar formulation with suitable excipients, is most effective, although an intramuscular bolus injection is also useful. Typically, the parenteral dose will be about 0.01 to about 100 mg/kg; preferably between 0.1 and 20 mg/kg, in a manner to maintain the concentration of drug in the plasma at a concentration effective to inhibit cathepsin K. The compounds are administered one to four times daily at a level to achieve a total daily dose of about 0.4 to about 400 mg/kg/day. The precise amount of an inventive compound which is therapeutically effective, and the route by which such compound is best administered, is readily determined by one of ordinary skill in the art by comparing the blood level of the agent to the concentration required to have a therapeutic effect.

The compounds of this invention may also be administered orally to the patient, in a manner such that the concentration of drug is sufficient to inhibit bone resorption or to achieve any other therapeutic indication as disclosed herein. Typically, a pharmaceutical composition containing the compound is administered at an oral dose of between about 0.1 to about 50 mg/kg in a manner consistent with the condition of the patient. Preferably the oral dose would be about 0.5 to about 20 mg/kg.

No unacceptable toxicological effects are expected when compounds of the present invention are administered in accordance with the present invention.

The compounds of this invention may be tested in one of several biological assays to determine the concentration of compound which is required to have a given pharmacological effect.

**Determination of cathepsin K proteolytic catalytic activity**

All assays for cathepsin K were carried out with human recombinant enzyme. Standard assay conditions for the determination of kinetic constants used a fluorogenic peptide substrate, typically Cbz-Phe-Arg-AMC, and were determined in 100 mM Na acetate at pH 5.5 containing 20 mM cysteine and 5 mM EDTA. Stock substrate solutions were prepared at concentrations of 10 or 20 mM in DMSO with 20 uM final substrate concentration in the assays. All assays contained 10% DMSO. Independent experiments found that this level of DMSO had no effect on enzyme activity or kinetic constants. All assays were conducted at ambient temperature. Product fluorescence (excitation at 360 nM; emission at 460 nM) was monitored with a Perceptive Biosystems Cytofluor II
fluorescent plate reader. Product progress curves were generated over 20 to 30 minutes following formation of AMC product.

**Inhibition studies**

Potential inhibitors were evaluated using the progress curve method. Assays were carried out in the presence of variable concentrations of test compound. Reactions were initiated by addition of enzyme to buffered solutions of inhibitor and substrate. Data analysis was conducted according to one of two procedures depending on the appearance of the progress curves in the presence of inhibitors. For those compounds whose progress curves were linear, apparent inhibition constants ($K_{i, app}$) were calculated according to equation 1 (Brandt et al., *Biochemistry*, 1989, 28, 140):

$$v = V_m A / [K_a (1 + l/K_{i, app}) + A]$$  \hspace{1cm} (1)

where $v$ is the velocity of the reaction with maximal velocity $V_m$, $A$ is the concentration of substrate with Michaelis constant of $K_a$, and $l$ is the concentration of inhibitor.

For those compounds whose progress curves showed downward curvature characteristic of time-dependent inhibition, the data from individual sets was analyzed to give $k_{obs}$ according to equation 2:

$$[AMC] = v_{ss} t + (v_0 - v_{ss}) [1 - \exp(-k_{obs} t)] / k_{obs}$$ \hspace{1cm} (2)

where $[AMC]$ is the concentration of product formed over time $t$, $v_0$ is the initial reaction velocity and $v_{ss}$ is the final steady state rate. Values for $k_{obs}$ were then analyzed as a linear function of inhibitor concentration to generate an apparent second order rate constant ($k_{obs} / inhibitor concentration$ or $k_{obs} / [I]$) describing the time-dependent inhibition. A complete discussion of this kinetic treatment has been fully described (Morrison et al., *Adv. Enzymol. Relat. Areas Mol. Biol.*, 1988, 61, 201).

One skilled in the art would consider any compound with a $K_i$ of less than 50 micromolar to be a potential lead compound. Preferably, the compounds used in the method of the present invention have a $K_i$ value of less than 1 micromolar. Most preferably, said compounds have a $K_i$ value of less than 100 nanomolar. 4-(R,S)-Amino-N-[(8-quinolinesulfonyl)-S-leucine]-3-tetrahydrofuran-3-one, a compound of formula (1), has a $K_i$ value that is greater than 10 micromolar.
Human Osteoclast Resorption Assay

Aliquots of osteoclastoma-derived cell suspensions were removed from liquid nitrogen storage, warmed rapidly at 37°C and washed x1 in RPMI-1640 medium by centrifugation (1000 rpm, 5 min at 4°C). The medium was aspirated and replaced with murine anti-HLA-DR antibody, diluted 1:3 in RPMI-1640 medium, and incubated for 30 min on ice. The cell suspension was mixed frequently.

The cells were washed x2 with cold RPMI-1640 by centrifugation (1000 rpm, 5 min at 4°C) and then transferred to a sterile 15 mL centrifuge tube. The number of mononuclear cells were enumerated in an improved Neubauer counting chamber.

Sufficient magnetic beads (5 / mononuclear cell), coated with goat anti-mouse IgG, were removed from their stock bottle and placed into 5 mL of fresh medium (this washes away the toxic azide preservative). The medium was removed by immobilizing the beads on a magnet and is replaced with fresh medium.

The beads were mixed with the cells and the suspension was incubated for 30 min on ice. The suspension was mixed frequently. The bead-coated cells were immobilized on a magnet and the remaining cells (osteoclast-rich fraction) were decanted into a sterile 50 mL centrifuge tube. Fresh medium was added to the bead-coated cells to dislodge any trapped osteoclasts. This wash process was repeated x10. The bead-coated cells were discarded.

The osteoclasts were enumerated in a counting chamber, using a large-bore disposable plastic pasteur pipette to charge the chamber with the sample. The cells were pelleted by centrifugation and the density of osteoclasts adjusted to 1.5x10^4/mL in EMEM medium, supplemented with 10% fetal calf serum and 1.7g/litre of sodium bicarbonate. 3 mL aliquots of the cell suspension (per treatment) were decanted into 15 mL centrifuge tubes. These cells were pelleted by centrifugation. To each tube 3 mL of the appropriate treatment was added (diluted to 50 uM in the EMEM medium). Also included were appropriate vehicle controls, a positive control (87MEM1 diluted to 100 ug/mL) and an isotype control (IgG2a diluted to 100 ug/mL). The tubes were incubate at 37°C for 30 min.

0.5 mL aliquots of the cells were seeded onto sterile dentine slices in a 48-well plate and incubated at 37°C for 2 h. Each treatment was screened in quadruplicate. The slices were washed in six changes of warm PBS (10 mL / well in a 6-well plate) and then placed into fresh treatment or control and incubated at 37°C for 48 h. The slices were then washed in phosphate buffered saline and fixed in 2% glutaraldehyde (in 0.2M sodium cacodylate) for 5 min., following which they were washed in water and incubated in buffer for 5 min at 37°C. The slices were then washed in cold water and incubated in cold acetate buffer / fast red garnet for 5 min at 4°C. Excess buffer was aspirated, and the slices were air dried following a wash in water.
The TRAP positive osteoclasts were enumerated by bright-field microscopy and were then removed from the surface of the dentine by sonication. Pit volumes were determined using the Nikon/Lasertec ILM21W confocal microscope.

Examples

Nuclear magnetic resonance spectra were recorded at either 250 or 400 MHz using, respectively, a Bruker AM 250 or Bruker AC 400 spectrometer. CDCl₃ is deuteriochloroform, DMSO-d₆ is hexadeuteriodimethylsulfoxide, and CD₃OD is tetradeteriromethanol. Chemical shifts are reported in parts per million (d) downfield from the internal standard tetramethylsilane. Abbreviations for NMR data are as follows: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, dd = doublet of doublets, dt = doublet of triplets, app = apparent, br = broad. J indicates the NMR coupling constant measured in Hertz. Continuous wave infrared (IR) spectra were recorded on a Perkin-Elmer 683 infrared spectrometer, and Fourier transform infrared (FTIR) spectra were recorded on a Nicolet Impact 400 D infrared spectrometer. IR and FTIR spectra were recorded in transmission mode, and band positions are reported in inverse wavenumbers (cm⁻¹). Mass spectra were taken on either VG 70 FE, PE Syx API III, or VG ZAB HF instruments, using fast atom bombardment (FAB) or electrospray (ES) ionization techniques. Elemental analyses were obtained using a Perkin-Elmer 240C elemental analyzer. Melting points were taken on a Thomas-Hoover melting point apparatus and are uncorrected. All temperatures are reported in degrees Celsius.

Analtech Silica Gel GF and E. Merck Silica Gel 60 F-254 thin layer plates were used for thin layer chromatography. Both flash and gravity chromatography were carried out on E. Merck Kieselgel 60 (230-400 mesh) silica gel.

Where indicated, certain of the materials were purchased from the Aldrich Chemical Co., Milwaukee, Wisconsin, Chemical Dynamics Corp., South Plainfield, New Jersey, and Advanced Chemtech, Louisville, Kentucky.

In the following synthetic examples, temperature is in degrees Centigrade (°C). Unless otherwise indicated, all of the starting materials were obtained from commercial sources. Without further elaboration, it is believed that one skilled in the art can, using the preceding description, utilize the present invention to its fullest extent. These Examples are given to illustrate the invention, not to limit its scope. Reference is made to the claims for what is reserved to the inventors hereunder.

Example 1
Preparation of 4-[[N\textsuperscript{2}-(benzyloxycarbonyl)-L-leucinyl]amino]-1-((2S)-4-methyl-2-[[[benzyloxycarbonyl]amino]pentanoyl]-3-pyrrolidinone

a.) 1-\textit{tert}-butoxycarbonyl-3-pyrrolidine

To a solution of 3-pyrroline (5.0 g, 72.35 mmol) in CH\textsubscript{2}Cl\textsubscript{2} (25 mL) at room was added di-t-butyl dicarbonate (16.58 g, 75.97 mmol) in CH\textsubscript{2}Cl\textsubscript{2} (50 mL). The reaction was stirred for ca. 1 hour whereupon it was concentrated in vacuo to give the BOC protected 3-pyrroline which was used directly in the following step without further purification: \textit{\textsuperscript{1}}H NMR (200 MHz, CD\textsubscript{3}OD) 5.12 (m, 2H), 3.92 (m, 4H), 1.38 (s, 9H).

b.) 1-\textit{tert}-butoxycarbonyl-3,4-epoxyoxypyrrolidine

To a solution of a compound of Example 1(a) (5.0 g, 29.5 mmol) in CH\textsubscript{2}Cl\textsubscript{2} (200 mL) was added NaHCO\textsubscript{3} (9.03 g, 118.2 mmol) and m-CPBA (15.29 g, 88.6 mmol). The reaction was stirred at room temperature overnight whereupon it was concentrated and filtered with petroleum ether. The petroleum ether layer was washed with saturated K\textsubscript{2}CO\textsubscript{3} (2x’s), water, brine, dried (MgSO\textsubscript{4}) and concentrated to give a clear colorless oil. To this mixture was then added a solution of N-phenyltrifluoromethanesulfonimide (22.53 g, 63.1 mmol) in anhydrous THF (40 mL) and the reaction was stirred at room temperature until TLC analysis indicated the complete consumption of starting material (1.5 h). The reaction was quenched by the addition of H\textsubscript{2}O (10 mL), concentrated to one half original volume, then diluted with CHCl\textsubscript{3} (200 mL) and washed with H\textsubscript{2}O. The aqueous layer was washed with fresh CHCl\textsubscript{3} (50 mL), the combined organic layers were washed with 10% Na\textsubscript{2}CO\textsubscript{3}, H\textsubscript{2}O, and brine, then dried (MgSO\textsubscript{4}), filtered and concentrated.
