(54) Title: QUINAZOLINE DERIVATIVES

(57) Abstract: A compound of formula (I) or a salt, ester or amide thereof; where X is O, or S, SO₂ or NR² or NR¹ wherein R¹ is hydrogen or C₁₋₆ alkyl, and R², R³, R⁴, R⁵, R⁶, R⁷, R⁸ and R⁹ are various specified organic groups. These compounds are inhibitors of aurora 2 kinase, and are useful in the treatment of cancer.
QUINAZOLINE DERIVATIVES

The present invention relates to certain quinazoline derivatives for use in the treatment of certain diseases in particular to proliferative disease such as cancer and in the preparation of medicaments for use in the treatment of proliferative disease, to novel quinazoline compounds and to processes for their preparation, as well as pharmaceutical compositions containing them as active ingredient.

Cancer (and other hyperproliferative disease) is characterised by uncontrolled cellular proliferation. This loss of the normal regulation of cell proliferation often appears to occur as the result of genetic damage to cellular pathways that control progress through the cell cycle.

In eukaryotes, the cell cycle is largely controlled by an ordered cascade of protein phosphorylation. Several families of protein kinases that play critical roles in this cascade have now been identified. The activity of many of these kinases is increased in human tumours when compared to normal tissue. This can occur by either increased levels of expression of the protein (as a result of gene amplification for example), or by changes in expression of co activators or inhibitory proteins.

The first identified, and most widely studied of these cell cycle regulators have been the cyclin dependent kinases (or CDKs). Activity of specific CDKs at specific times is essential for both initiation and coordinated progress through the cell cycle. For example, the CDK4 protein appears to control entry into the cell cycle (the G0-G1-S transition) by phosphorylating the retinoblastoma gene product pRb. This stimulates the release of the transcription factor E2F from pRb, which then acts to increase the transcription of genes necessary for entry into S phase. The catalytic activity of CDK4 is stimulated by binding to a partner protein, Cyclin D. One of the first demonstrations of a direct link between cancer and the cell cycle was made with the observation that the Cyclin D1 gene was amplified and cyclin D protein levels increased (and hence the activity of CDK4 increased) in many human tumours (Reviewed in Sherr, 1996, Science 274: 1672-1677; Pines, 1995, Seminars in Cancer Biology 6: 63-72). Other studies (Loda et al., 1997, Nature Medicine 3(2): 231-234; Gemma et al., 1996, International Journal of Cancer 68(5): 605-11; Elledge et al. 1996, Trends in Cell Biology 6; 388-392) have shown that negative regulators of CDK function are frequently down regulated or deleted in human tumours again leading to inappropriate activation of these kinases.
More recently, protein kinases that are structurally distinct from the CDK family have been identified which play critical roles in regulating the cell cycle and which also appear to be important in oncogenesis. These include the newly identified human homologues of the *Drosophila* aurora and *S. cerevisiae* Ipl1 proteins. *Drosophila* aurora and *S. cerevisiae* Ipl1, which are highly homologous at the amino acid sequence level, encode serine/threonine protein kinases. Both aurora and Ipl1 are known to be involved in controlling the transition from the G2 phase of the cell cycle through mitosis, centrosome function, formation of a mitotic spindle and proper chromosome separation / segregation into daughter cells. The two human homologues of these genes, termed aurora1 and aurora2, encode cell cycle regulated protein kinases. These show a peak of expression and kinase activity at the G2/M boundary (aurora2) and in mitosis itself (aurora1). Several observations implicate the involvement of human aurora proteins, and particularly aurora2 in cancer. The aurora2 gene maps to chromosome 20q13, a region that is frequently amplified in human tumours including both breast and colon tumours. Aurora2 may be the major target gene of this region, since aurora2 DNA is amplified and aurora2 mRNA overexpressed in greater than 50% of primary human colorectal cancers. In these tumours aurora2 protein levels appear greatly elevated compared to adjacent normal tissue. In addition, transfection of rodent fibroblasts with human aurora2 leads to transformation, conferring the ability to grow in soft agar and form tumours in nude mice (Bischoff et al., 1998, The EMBO Journal. 17(11): 3052-3065). Other work (Zhou et al., 1998, Nature Genetics. 20(2): 189-93) has shown that artificial overexpression of aurora2 leads to an increase in centrosome number and an increase in aneuploidy.

Importantly, it has also been demonstrated that abrogation of aurora2 expression and function by antisense oligonucleotide treatment of human tumour cell lines (WO 97/22702 and WO 99/37788) leads to cell cycle arrest in the G2 phase of the cell cycle and exerts an antiproliferative effect in these tumour cell lines. This indicates that inhibition of the function of aurora2 will have an antiproliferative effect that may be useful in the treatment of human tumours and other hyperproliferative diseases.

A number of quinazoline derivatives have been proposed hitherto for use in the inhibition of various kinases. Examples of such proposals are included in US Patent No 5646153.
The applicants have found a series of compounds which inhibit the effect of the aurora2 kinase and which are thus of use in the treatment of proliferative disease such as cancer, in particular in such diseases such as colorectal or breast cancer where aurora 2 kinase is known to be active.

In a further embodiment, R¹ is a group NR¹^R¹³ where R¹² and R¹³ together with
the nitrogen atom to which they are attached or an optionally substituted heterocyclic ring,
and in particular a non-aromatic ring such as morpholine or piperidine.

Preferably R¹ is hydrogen. Suitably R¹⁴ is hydrogen or a small substituent such as
halo, C¹⁴ alkyl or C¹⁴-alkoxy such as methoxy.

Preferably both R¹ and R¹⁴ are hydrogen.

Preferably R² and R³ are independently selected from a group -X¹R¹⁶ where X¹ is
oxygen and R¹⁶ is as defined above. Particular groups R¹⁶ are those in group (1) above,
especially alkyl such as methyl or halo substituted alkyl.

In a preferred embodiment, at least one group R² or R³, preferably R³,
comprises a chain of at least 3 and preferably at least 4 optionally substituted carbon
atoms or heteroatoms such as oxygen, nitrogen or sulphur. Most preferably the chain is
substituted by a polar group which assists in solubility.

Preferably in this case, X¹ is oxygen and R¹⁶ includes a methylene group directly
adjacent X¹. Preferably where bridging alkylene, alkenylene or alkynylene groups Rᵃ,
Rᵇ, Rᶜ, Rᵈ, Rᵉ, Rᶠ, Rᵍ, Rʰ, Rᵢ, Rʲ, Rʳ, Rˢ, Rᵗ, Rᵘ, Rʳ, Rˢ, Rᵗ, Rᵘ, Rʳ, Rˢ and
R⁶ are present, at least one such group includes a substituent and in particular a hydroxy
substituent.

Suitably R³ is a group XR¹⁶. Preferably in this case, X¹ is oxygen and R¹⁶ is
selected from a group of formula (1), (3), (6) or (10) above and preferably selected from
groups (1) or (10) above. Particular groups R¹⁶ are those in group (1) above, especially
alkyl such as methyl or halo substituted alkyl, or those in group (10) above. In one
preferred embodiment, at least one of R² or R³ is a group O₈-alkylR⁴² and R⁴² is a
heterocyclic ring such as an N-linked morpholine ring such as 3-morpholinopropoxy.

Other preferred groups for R³ are groups of formula (3) above in particular those
where X³ is -NR³²⁻.

Suitably R² is selected from, halo, cyano, nitro, trifluoromethyl, C₁₃-alkyl,
-NR¹⁴R¹⁵ (wherein R¹⁴ and R¹⁵, which may be the same or different, each represents
hydrogen or C₁₃-alkyl), or a group -X¹R¹⁶. Preferred examples of -X¹R¹⁶ for R² include
those listed above in relation to R³.

Other examples for R² and R³ include methoxy or 3,3,3-trifluorooxy.

Preferably X is NH or O and is most preferably NH.
Particular examples of groups $R^8$ or $R^9$ include hydrogen, halo, C$_{1-4}$alkoxy such as methoxy, or ethoxy, cyano, trifluoromethyl, or phenyl. Preferably $R^8$ and $R^9$ are hydrogen.

Suitably, at least one substituent is positioned at the 4-position on the phenyl.

Thus in a preferred embodiment, the invention provides compounds of formula (IB)

![Chemical Structure](IB)

where all variable groups are as defined in relation to formula (I) or (IA).

Suitable prodrugs of compounds of formula (I) are groups which enhance solubility and include phosphates and sulphates, in particular phosphates as well as alkyl, aryl or aralkyl derivatives thereof such as dibenzylphosphate. The prodrug moiety may be attached at any suitable position in the molecule, for example as a derivative of a hydroxy group, but in particular, may be advantageously present on one or more of groups $R^1$, $R^2$, $R^3$ or $R^4$, and preferably at $R^2$ or $R^3$.

Suitable pharmaceutically acceptable salts of compounds of formula (I) include acid addition salts such as methanesulfonate, fumarate, hydrochloride, hydrobromide, citrate, maleate and salts formed with phosphoric and sulphuric acid. There may be more than one cation or anion depending on the number of charged functions and the valency of the cations or anions. Where the compound of formula (I) includes an acid functionality, salts may be base salts such as an alkali metal salt for example sodium, an alkaline earth metal salt for example calcium or magnesium, an organic amine salt for example triethylamine, morpholine, $N$-methylpiperidine, $N$-ethylpiperidine, procaine,
dibenzyamine, N,N-dibenzylethylamine or amino acids for example lysine. A preferred pharmaceutically acceptable salt is a sodium salt.

An in vivo hydrolysable ester of a compound of the formula (I) containing carboxy or hydroxy group is, for example, a pharmaceutically acceptable ester which is hydrolysed in the human or animal body to produce the parent acid or alcohol.

Suitable pharmaceutically acceptable esters for carboxy include C_{1,6}alkyl esters such as methyl or ethyl esters, C_{1,6}alkoxymethyl esters for example methoxymethyl, C_{1,6}alkanoyloxymethyl esters for example pivaloyloxymethyl, phthalidyl esters, C_{3,8}cycloalkoxy-carbonyloxyC_{1,6}alkyl esters for example 1-cyclohexylcarbonyloxyethyl; 1,3-dioxolen-2-onylmethyl esters for example 5-methyl-1,3-dioxolen-2-onylmethyl; and C_{1,6}alkoxycarbonyloxyethyl esters for example 1-methoxycarbonyloxyethyl and may be formed at any carboxy group in the compounds of this invention.

An in vivo hydrolysable ester of a compound of the formula (I) containing a hydroxy group includes inorganic esters such as phosphate esters and \( \alpha \)-acyloyxalkyl ethers and related compounds which as a result of the in vivo hydrolysis of the ester breakdown to give the parent hydroxy group. Examples of \( \alpha \)-acyloyxalkyl ethers include acetoxyethoxy and 2,2-dimethylpropionyloxymethoxy. A selection of in vivo hydrolysable ester forming groups for hydroxy include alkanoyl, benzoyl, phenylacetyl and substituted benzoyl and phenylacetyl, alkoxycarbonyl (to give alkyl carbonate esters), dialkylcarbamoyl and \( N \)-(dialkylaminoethyl)-\( N \)-alkylcarbamoyl (to give carbamates), dialkylaminoacetanoyl and carboxyacetyl.

Suitable amides are derived from compounds of formula (I) which have a carboxy group which is derivatised into an amide such as a N-C_{1,6}alkyl and N,N-di-(C_{1,6}alkyl)amide such as N-methyl, N-ethyl, N-propyl, N,N-dimethyl, N-ethyl-N-methyl or N,N-diethylamide.

Esters which are not in vivo hydrolysable may be useful as intermediates in the production of the compounds of formula (I).

Particular examples of compounds of formula (I) are set out in Table 1.

* geometry of double bond is cis (Z) not trans (E)

Compounds of formula (I) may be prepared by various methods which would be apparent from the literature. For example compounds of formula (I) may be prepared by reacting a compound of formula (II)
where X, $R^8$ and $R^9$ are as defined in relation to formula (I), $R^{1'}$, $R^{2'}$, $R^{3'}$, $R^{4'}$ are groups $R^1$, $R^2$, $R^3$, $R^4$ as defined in relation to formula (I) respectively, or precursors thereof; and $R^{85}$ is a leaving group, with a compound of formula (III)

$$\text{(III)}$$

where $R^6$ are $R^7$ are as defined in relation to formula (I), $R^{5'}$ is a group $R^5$ as defined in relation to formula (I) or a precursor group therefore; and thereafter if desired or necessary, converting any precursor groups $R^{1'}$, $R^{2'}$, $R^{3'}$, $R^{4'}$ or $R^{5'}$ to groups $R^1$, $R^2$, $R^3$, $R^4$ or $R^5$ respectively, or changing a group $R^5$ to a different such group.

Suitable leaving groups for $R^{85}$ include halo such as chloro or iodo, mesylate and tosylate. The reaction is suitably effected in the presence of a base such as triethylamine, in an an organic solvent such as acetonitrile or alcohol like isopropanol, at elevated temperatures, conveniently at the reflux temperature of the solvent.

Suitably the compound of formula (III) is prepared in situ, for example by reducing a compound of formula (IV)

$$\text{(IV)}$$
where \( R^5, R^6 \) and \( R^7 \) are as defined in relation to formula (I), with a reducing agent such as tri(o-tolyl)phosphine in the presence of a catalyst such as a palladium catalyst, for instance palladium acetate.

Compounds of formula (II) and (IV) are either known compounds or they can be derived from known compounds by conventional methods.

The conversion of one group \( R^5 \) to another such group can be readily effected using conventional chemistry. For example compounds of formula (I) where \( R^5 \) is hydroxy can be converted to amides (where \( R^5 \) is a group \( NR^{12}R^{13} \)) using known methods and in particular by reacting the compound of formula (I) where \( R^5 \) is OH with an amine of formula \( HNR^{12}R^{13} \) in the presence of a base such as a carbodiimide.

Conversion of precursor groups \( R^1', R^2', R^3', R^4' \) or \( R^5' \) respectively may be carried out by conventional chemistry. Preferably \( R^1', R^2', R^3' \) and \( R^4' \) are equivalent to groups \( R^1, R^2, R^3 \) and \( R^4 \) respectively so that no conversions are required.

Compounds of formula (I) are inhibitors of aurora 2 kinase. As a result, these compounds can be used to treat disease mediated by these agents, in particular proliferative disease.

According to a further aspect of the invention there is provided a compound of the formula (I) as defined herein, or a salt, ester, amide or prodrug thereof, and in particular a pharmaceutically acceptable salt or an \textit{in vivo} hydrolysable ester thereof, for use in a method of treatment of the human or animal body by therapy. In particular, the compounds are used in methods of treatment of proliferative disease such as cancer and in particular cancers such as colorectal or breast cancer where aurora 2 is upregulated.

According to a further aspect of the present invention there is provided a method for inhibiting aurora 2 kinase in a warm blooded animal, such as man, in need of such treatment, which comprises administering to said animal an effective amount of a compound of formula (I), or a salt, ester, amide or prodrug thereof, and in particular a pharmaceutically acceptable salt, or an \textit{in vivo} hydrolysable ester thereof.

The invention also provides a pharmaceutical composition comprising a compound of formula (I) as defined herein, or a salt, ester, amide or prodrug thereof, and in particular a pharmaceutically acceptable salt, or an \textit{in vivo} hydrolysable ester thereof,
25
in combination with at pharmaceutically acceptable carrier. Preferred compounds of
formula (I) for use in the compositions of the invention are as described above.

The compositions of the invention may be in a form suitable for oral use (for
example as tablets, lozenges, hard or soft capsules, aqueous or oily suspensions,
emulsions, dispersible powders or granules, syrups or elixirs), for topical use (for
example as creams, ointments, gels, or aqueous or oily solutions or suspensions), for
administration by inhalation (for example as a finely divided powder or a liquid aerosol),
for administration by insufflation (for example as a finely divided powder) or for
parenteral administration (for example as a sterile aqueous or oily solution for
intravenous, subcutaneous, intramuscular or intramuscular dosing or as a suppository for
rectal dosing).

The compositions of the invention may be obtained by conventional procedures
using conventional pharmaceutical excipients, well known in the art. Thus, compositions
intended for oral use may contain, for example, one or more colouring, sweetening,
flavouring and/or preservative agents.

Suitable pharmaceutically acceptable excipients for a tablet formulation include,
for example, inert diluents such as lactose, sodium carbonate, calcium phosphate or
calcium carbonate, granulating and disintegrating agents such as corn starch or algenic
acid; binding agents such as starch; lubricating agents such as magnesium stearate,
stearic acid or talc; preservative agents such as ethyl or propyl p-hydroxybenzoate, and
anti-oxidants, such as ascorbic acid. Tablet formulations may be uncoated or coated
either to modify their disintegration and the subsequent absorption of the active
ingredient within the gastrointestinal track, or to improve their stability and/or
appearance, in either case, using conventional coating agents and procedures well known
in the art.

Compositions for oral use may be in the form of hard gelatin capsules in which
the active ingredient is mixed with an inert solid diluent, for example, calcium
carbonate, calcium phosphate or kaolin, or as soft gelatin capsules in which the active
ingredient is mixed with water or an oil such as peanut oil, liquid paraffin, or olive oil.

Aqueous suspensions generally contain the active ingredient in finely powdered
form together with one or more suspending agents, such as sodium
carboxymethylcellulose, methylcellulose, hydroxypropylmethylcellulose, sodium
alginate, polyvinyl-pyrrolidone, gum tragacanth and gum acacia; dispersing or wetting agents such as lecithin or condensation products of an alkylene oxide with fatty acids (for example polyoxyethylene stearate), or condensation products of ethylene oxide with long chain aliphatic alcohols, for example heptadecaethyleneoxyctanol, or condensation products of ethylene oxide with partial esters derived from fatty acids and a hexitol such as polyoxyethylene sorbitol monooleate, or condensation products of ethylene oxide with long chain aliphatic alcohols, for example heptadecaethyleneoxyctanol, or condensation products of ethylene oxide with partial esters derived from fatty acids and a hexitol such as polyoxyethylene sorbitol monooleate, or condensation products of ethylene oxide with partial esters derived from fatty acids and hexitol anhydrides, for example polyethylene sorbitan monooleate. The aqueous suspensions may also contain one or more preservatives (such as ethyl or propyl p-hydroxybenzoate, anti-oxidants (such as ascorbic acid), colouring agents, flavouring agents, and/or sweetening agents (such as sucrose, saccharine or aspartame).

Oily suspensions may be formulated by suspending the active ingredient in a vegetable oil (such as arachis oil, olive oil, sesame oil or coconut oil) or in a mineral oil (such as liquid paraffin). The oily suspensions may also contain a thickening agent such as beeswax, hard paraffin or cetyl alcohol. Sweetening agents such as those set out above, and flavouring agents may be added to provide a palatable oral preparation. These compositions may be preserved by the addition of an anti-oxidant such as ascorbic acid.

Dispersible powders and granules suitable for preparation of an aqueous suspension by the addition of water generally contain the active ingredient together with a dispersing or wetting agent, suspending agent and one or more preservatives. Suitable dispersing or wetting agents and suspending agents are exemplified by those already mentioned above. Additional excipients such as sweetening, flavouring and colouring agents, may also be present.

The pharmaceutical compositions of the invention may also be in the form of oil-in-water emulsions. The oily phase may be a vegetable oil, such as olive oil or arachis oil, or a mineral oil, such as for example liquid paraffin or a mixture of any of these. Suitable emulsifying agents may be, for example, naturally-occurring gums such as gum acacia or gum tragacanth, naturally-occurring phosphatides such as soya bean, lecithin, an esters or partial esters derived from fatty acids and hexitol anhydrides (for
example sorbitan monooleate) and condensation products of the said partial esters with ethylene oxide such as polyoxyethylene sorbitan monooleate. The emulsions may also contain sweetening, flavouring and preservative agents.

Syrups and elixirs may be formulated with sweetening agents such as glycerol, propylene glycol, sorbitol, aspartame or sucrose, and may also contain a demulcent, preservative, flavouring and/or colouring agent.

The pharmaceutical compositions may also be in the form of a sterile injectable aqueous or oily suspension, which may be formulated according to known procedures using one or more of the appropriate dispersing or wetting agents and suspending agents, which have been mentioned above. A sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally-acceptable diluent or solvent, for example a solution in 1,3-butanediol.

Suppository formulations may be prepared by mixing the active ingredient with a suitable non-irritating excipient which is solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum to release the drug. Suitable excipients include, for example, cocoa butter and polyethylene glycols.

Topical formulations, such as creams, ointments, gels and aqueous or oily solutions or suspensions, may generally be obtained by formulating an active ingredient with a conventional, topically acceptable, vehicle or diluent using conventional procedure well known in the art.

Compositions for administration by insufflation may be in the form of a finely divided powder containing particles of average diameter of, for example, 30μ or much less, the powder itself comprising either active ingredient alone or diluted with one or more physiologically acceptable carriers such as lactose. The powder for insufflation is then conveniently retained in a capsule containing, for example, 1 to 50mg of active ingredient for use with a turbo-inhaler device, such as is used for insufflation of the known agent sodium cromoglycate.

Compositions for administration by inhalation may be in the form of a conventional pressurised aerosol arranged to dispense the active ingredient either as an aerosol containing finely divided solid or liquid droplets. Conventional aerosol propellants such as volatile fluorinated hydrocarbons or hydrocarbons may be used and
the aerosol device is conveniently arranged to dispense a metered quantity of active ingredient.

For further information on Formulation the reader is referred to Chapter 25.2 in Volume 5 of Comprehensive Medicinal Chemistry (Corwin Hansch; Chairman of Editorial Board), Pergamon Press 1990.

The amount of active ingredient that is combined with one or more excipients to produce a single dosage form will necessarily vary depending upon the host treated and the particular route of administration. For example, a formulation intended for oral administration to humans will generally contain, for example, from 0.5 mg to 2 g of active agent compounded with an appropriate and convenient amount of excipients which may vary from about 5 to about 98 percent by weight of the total composition. Dosage unit forms will generally contain about 1 mg to about 500 mg of an active ingredient. For further information on Routes of Administration and Dosage Regimes the reader is referred to Chapter 25.3 in Volume 5 of Comprehensive Medicinal Chemistry (Corwin Hansch; Chairman of Editorial Board), Pergamon Press 1990.

The size of the dose for therapeutic or prophylactic purposes of a compound of the Formula I will naturally vary according to the nature and severity of the conditions, the age and sex of the animal or patient and the route of administration, according to well known principles of medicine. As mentioned above, compounds of the Formula I are useful in treating diseases or medical conditions which are due alone or in part to the effects of aurora 2 kinase.

In using a compound of the Formula I for therapeutic or prophylactic purposes it will generally be administered so that a daily dose in the range, for example, 0.5 mg to 75 mg per kg body weight is received, given if required in divided doses. In general lower doses will be administered when a parenteral route is employed. Thus, for example, for intravenous administration, a dose in the range, for example, 0.5 mg to 30 mg per kg body weight will generally be used. Similarly, for administration by inhalation, a dose in the range, for example, 0.5 mg to 25 mg per kg body weight will be used. Oral administration is however preferred.

A further aspect of the invention comprises a compound of formula (I) as defined above, or or a salt, ester, amide or prodrug thereof, and in particular a pharmaceutically acceptable salt or in vivo hydrolysable ester thereof, for use in the preparation of a
medicament for the treatment of proliferative disease. Preferred compounds of formula (I) for this purpose are as described above.

The invention will now be illustrated in the following non limiting Examples, in which standard techniques known to the skilled chemist and techniques analogous to those described in these Examples may be used where appropriate, and in which, unless otherwise stated:

(i) evaporations were carried out by rotary evaporation \textit{in vacuo} and work up procedures were carried out after removal of residual solids such as drying agents by filtration;

(ii) operations were carried out at ambient temperature, typically in the range 18-25°C and in air unless stated, or unless the skilled person would otherwise operate under an atmosphere of an inert gas such as argon;

(iii) column chromatography (by the flash procedure) and medium pressure liquid chromatography (MPLC) were performed on Merck Kieselgel silica (Art. 9385) or on Merck Lichroprep RP-18 (Art. 9303) reversed-phase silica, obtained from E. Merck, Darmstadt, Germany; bond elute chromatography was performed using Varian Mega Bond Elut cartridges (10 g, order code 1225-6034), obtained from Varian Sample Preparation Products, California, USA;

**Example 1 - Preparation of Compound No. 1 in Table 1**

Palladium (II) acetate (303 mg, 1.35 mmol) was added to a solution of 4-(4-idoanilino)-6,7-dimethoxyquinazoline (6.00g, 13.5 mmol), ethyl acrylate (1.35 g, 13.5 mmol) and tri(o-tolyl)phosphine (821 mg, 2.70 mmol) in a mixture of triethylamine (60 ml) and acetonitrile (200 ml) and the reaction was heated at reflux for 20 hours under an inert atmosphere. a) Potassium carbonate (62.2 g, 450 mmol) was added to a solution of ethyl vanillate (58.9 g, 300 mmol) in dimethylformamide (400 ml) and the reaction heated to 120 °C. 2,2,2-Trifluoroethyl methanesulphonate (63.4 g, 360 mmol) was added over 15 minutes and the reaction heated at 120 °C for 15 hours. The reaction was cooled to ambient temperature, diethyl ether (400 ml) was added and the reaction was filtered. The filtrate was evaporated in vacuo and the residue was taken up in a mixture of diethyl ether (375 ml) and isohexane (375 ml). The organic layer was concentrated in vacuo to a total volume of 250 ml and the solid which crystallised out was collected by suction filtration. Drying of the solid in vacuo yielded ethyl 4-(2,2,2-trifluoroethoxy)-3-methoxybenzoate (43.0 g, 52 % yield) as a white crystalline solid:

\[ ^1 \text{H-NMR (DMSO d_6)} : 7.57 (dd, 1H, J = 2, 8 Hz), 7.49 (d, 1H, J = 2 Hz), 7.18 (d, 1H, J = 8 Hz), 5.81 (q, 2H, J = 7 Hz), 5.29 (q, 2H, J = 7 Hz), 3.82 (s, 3H), 1.30 (t, 3H, J = 7 Hz) : \]

MS (+ve ESI) : 279 (M+H)^+.

b) Concentrated sulphuric acid (64 ml) and concentrated nitric acid (10.0 ml, 0.152 mol) were added cautiously, over 1 hour, to a two-phase system containing a stirred solution of ethyl 4-(2,2,2-trifluoroethoxy)-3-methoxybenzoate (35.3 g, 0.127 mol) in dichloromethane (340 ml), acetic acid (173 ml) and water (40 ml) at 5 °C. The reaction was allowed to warm to ambient temperature over 60 hours (with vigorous mechanical stirring), the aqueous phase was separated, and the organic phase washed with water (6 x 250 ml). The organic phase was concentrated to a total volume of ~200 ml, isohexane (150 ml) was added and the solid which precipitated was collected by suction filtration. Drying of the solid in vacuo yielded ethyl 3-methoxy-4-(2,2,2-trifluoroethoxy)-6-nitrobenzoate (21.7 g, 52 % yield) as a yellow solid. The mother liquors contained a mixture of product (28%) and starting material (72%) which was recycled in a latter reaction:

ethyl acetate (750 ml) was stirred under an atmosphere of hydrogen for 18 hours.

Removal of the catalyst by filtration, followed by solvent evaporation in vacuo yielded ethyl 3-methoxy-4-((2,2,2-trifluoroethoxy)-6-aminobenzoate (20.2 g, 93 % yield) as a pale brown solid:

The mixture was allowed to cool to ambient temperature, ethanol (150 ml) was added and the reaction allowed to stand for 18 hours. Collection of the solid which had precipitated by suction filtration, followed by washing with ethanol (2 x 50 ml) and drying in vacuo, yielded 6-methoxy-7-(2,2,2-trifluoroethoxy)-3,4-dihydroquinazolin-4-one (15.8 g, 84 % yield) as a pale brown crystalline solid:

The reaction was cooled, excess thionyl chloride was removed in vacuo and the residue was azeotroped with toluene (2 x 50 ml) to remove the last of the thionyl chloride. The residue was taken up in dichloromethane (550 ml), the solution was washed with saturated aqueous sodium hydrogen carbonate solution (2 x 250 ml) and the organic phase was dried over magnesium sulphate. Solvent evaporation in vacuo yielded 4-chloro-6-methoxy-7-(2,2,2-trifluoroethoxy)quinazoline (16.3 g, 97 % yield) as a cream solid:

Biological Data

The compounds of the invention inhibit the serine/threonine kinase activity of the aurora2 kinase and thus inhibit the cell cycle and cell proliferation. These properties may be assessed, for example, using one or more of the procedures set out below:

(a) In Vitro aurora2 kinase inhibition test

This assay determines the ability of a test compound to inhibit serine/threonine kinase activity. DNA encoding aurora2 may be obtained by total gene synthesis or by cloning. This DNA may then be expressed in a suitable expression system to obtain polypeptide with serine/threonine kinase activity. In the case of aurora2, the coding sequence was isolated from cDNA by polymerase chain reaction (PCR) and cloned into the BamH1 and Not1 restriction endonuclease sites of the baculovirus expression vector pFastBac HTc (GibcoBRL/Life technologies). The 5' PCR primer contained a recognition sequence for the restriction endonuclease BamH1 5' to the aurora2 coding sequence. This allowed the insertion of the aurora2 gene in frame with the 6 histidine residues, spacer region and rTEV protease cleavage site encoded by the pFastBac HTc vector. The 3' PCR primer replaced the aurora2 stop codon with additional coding
sequence followed by a stop codon and a recognition sequence for the restriction endonuclease Not1. This additional coding sequence (5' TAC CCA TAC GAT GTT CCA GAT TAC GCT TCT TAA 3') encoded for the polypeptide sequence YPYDVPDYAS. This sequence, derived from the influenza hemagglutin protein, is frequently used as a tag epitope sequence that can be identified using specific monoclonal antibodies. The recombinant pFastBac vector therefore encoded for an N-terminally 6 his tagged, C terminally influenza hemagglutin epitope tagged aurora2 protein. Details of the methods for the assembly of recombinant DNA molecules can be found in standard texts, for example Sambrook et al. 1989, Molecular Cloning - A Laboratory Manual, 2nd Edition, Cold Spring Harbor Laboratory press and Ausubel et al. 1999, Current Protocols in Molecular Biology, John Wiley and Sons Inc.

Production of recombinant virus can be performed following manufacturer's protocol from GibcoBRL. Briefly, the pFastBac-1 vector carrying the aurora2 gene was transformed into E. coli DH10Bac cells containing the baculovirus genome (bacmid DNA) and via a transposition event in the cells, a region of the pFastBac vector containing gentamycin resistance gene and the aurora2 gene including the baculovirus polyhedrin promoter was transposed directly into the bacmid DNA. By selection on gentamycin, kanamycin, tetracycline and X-gal, resultant white colonies should contain recombinant bacmid DNA encoding aurora2. Bacmid DNA was extracted from a small scale culture of several BH10Bac white colonies and transfected into Spodoptera frugiperda Sf21 cells grown in TC100 medium (GibcoBRL) containing 10% serum using CellFECTIN reagent (GibcoBRL) following manufacturer's instructions. Virus particles were harvested by collecting cell culture medium 72 hrs post transfection. 0.5 mls of medium was used to infect 100 ml suspension culture of Sf21s containing 1 x 10^7 cells/ml. Cell culture medium was harvested 48 hrs post infection and virus titre determined using a standard plaque assay procedure. Virus stocks were used to infect Sf9 and "High 5" cells at a multiplicity of infection (MOI) of 3 to ascertain expression of recombinant aurora2 protein.

For the large scale expression of aurora2 kinase activity, Sf21 insect cells were grown at 28°C in TC100 medium supplemented with 10% foetal calf serum (Viralex) and 0.2% F68 Pluronic (Sigma) on a Wheaton roller rig at 3 r.p.m. When the cell density reached 1.2x10^6 cells ml^-1 they were infected with plaque-pure aurora2 recombinant
virus at a multiplicity of infection of 1 and harvested 48 hours later. All subsequent purification steps were performed at 4°C. Frozen insect cell pellets containing a total of 2.0 x 10^8 cells were thawed and diluted with lysis buffer (25 mM HEPES (N-[2-hydroxyethyl]piperazine-N'-[2-ethanesulphonic acid]) pH7.4 at 4°C, 100 mM KCl, 25 mM NaF, 1 mM Na3VO4, 1 mM PMSF (phenylmethylsulphonyl fluoride), 2 mM 2-mercaptoethanol, 2 mM imidazole, 1 μg/ml aprotinin, 1 μg/ml pepstatin, 1 μg/ml leupeptin), using 1.0 ml per 3 x 10^7 cells. Lysis was achieved using a dounce homogeniser, following which the lysate was centrifuged at 41,000g for 35 minutes. Aspirated supernatant was pumped onto a 5 mm diameter chromatography column containing 500 μl Ni NTA (nitrilo-tri-acetic acid) agarose (Qiagen, product no. 30250) which had been equilibrated in lysis buffer. A baseline level of UV absorbance for the eluent was reached after washing the column with 12 ml of lysis buffer followed by 7 ml of wash buffer (25 mM HEPES pH7.4 at 4°C, 100 mM KCl, 20 mM imidazole, 2 mM 2-mercaptoethanol). Bound aurora2 protein was eluted from the column using elution buffer (25 mM HEPES pH7.4 at 4°C, 100 mM KCl, 400 mM imidazole, 2 mM 2-mercaptoethanol). An elution fraction (2.5 ml) corresponding to the peak in UV absorbance was collected. The elution fraction, containing active aurora2 kinase, was dialysed exhaustively against dialysis buffer (25 mM HEPES pH7.4 at 4°C, 45% glycerol (v/v), 100 mM KCl, 0.25% Nonidet P40 (v/v), 1 mM dithiothreitol).

Each new batch of aurora2 enzyme was titrated in the assay by dilution with enzyme diluent (25 mM Tris-HCl pH7.5, 12.5 mM KCl, 0.6 mM DTT). For a typical batch, stock enzyme is diluted 1 in 666 with enzyme diluent & 20 μl of dilute enzyme is used for each assay well. Test compounds (at 10 mM in dimethylsulphoxide (DMSO)) were diluted with water & 10 μl of diluted compound was transferred to wells in the assay plates. “Total” & “blank” control wells contained 2.5% DMSO instead of compound. Twenty microlitres of freshly diluted enzyme was added to all wells, apart from “blank” wells. Twenty microlitres of enzyme diluent was added to “blank” wells. Twenty microlitres of reaction mix (25 mM Tris-HCl, 78.4 mM KCl, 2.5 mM NaF, 0.6 mM dithiothreitol, 6.25 mM MnCl2, 6.25 mM ATP, 7.5 μM peptide substrate [biotin-LRRWSLGLRWSLGLRRWSLGLRRWSLGLR]) containing 0.2 μCi [γ^33P]ATP (Amersham Pharmacia, specific activity ≥2500 Ci/mmol) was then added to all test wells to start the reaction. The plates were incubated at room temperature for 60 minutes. To
stop the reaction 100μl 20% v/v orthophosphoric acid was added to all wells. The peptide substrate was captured on positively-charged nitrocellulose P30 filtermat (Whatman) using a 96-well plate harvester (TomTek) & then assayed for incorporation of ³³P with a Beta plate counter. “Blank” (no enzyme) and “total” (no compound) control values were used to determine the dilution range of test compound which gave 50% inhibition of enzyme activity.

In this test, compound 18 in Table 1 gave 50% inhibition of enzyme activity at a concentration of 0.117μM.

(b) In Vitro cell proliferation assay

These and other assays can be used to determine the ability of a test compound to inhibit the growth of adherent mammalian cell lines, for example the human tumour cell line MCF7.

Assay 1

MCF-7 (ATCC HTB-22) or other adherent cells were typically seeded at 1 x 10⁸ cells per well (excluding the peripheral wells) in DMEM (Sigma Aldrich) without phenol red, plus 10% foetal calf serum, 1% L-glutamine and 1% penicillin/streptomycin in 96 well tissue culture treated clear plates (Costar). The following day (day 1), the media was removed from a no treatment control plate and the plate stored at -80°C. The remaining plates were dosed with compound (diluted from 10mM stock in DMSO using DMEM (without phenol red, 10% FCS, 1% L-glutamine, 1% penicillin/streptomycin). Untreated control wells were included on each plate. After 3 days in the presence / absence of compound (day 4) the media was removed and the plates stored at -80°C. Twenty four hours later the plates were thawed at room temperature and cell density determined using the CyQUANT cell proliferation assay kit (c-7026/c-7027 Molecular Probes Inc.) according to manufacturers directions. Briefly, 200μl of a cell lysis / dye mixture (10μl of 20X cell lysis buffer B, 190μl of sterile water, 0.25μl of CYQUANT GR dye) was added to each well and the plates incubated at room temperature for 5 minutes in the dark. The fluorescence of the wells was then measured using a fluorescence microplate reader (gain 70, 2 reads per well, 1 cycle with excitation 485nm and emission 530nm using a CytoFluor plate reader (PerSeptive Biosystems Inc.)). The values from day 1 and day 4 (compound treated) together with the values from the untreated cells were used to determine the dilution range of a test compound that gave
50% inhibition of cell proliferation. Compound 18 in Table 1 was effective in this test at 6.38μM.

These values could also be used to calculate the dilution range of a test compound at which the cell density dropped below the day 1 control value. This indicates the cytotoxicity of the compound.

**Assay 2**

This assay determines the ability of a test compound to inhibit the incorporation of the thymidine analogue, 5'-bromo-2'-deoxy-uridine (BrdU) into cellular DNA. MCF-7 or other adherent cells were typically seeded at 0.8 x 10⁵ cells per well in DMEM (Sigma Aldrich) without phenol red, plus 10% foetal calf serum, 1% L-glutamine and 1% penicillin/streptomycin (50μl / well) in 96 well tissue culture treated 96 well plates (Costar) and allowed to adhere overnight. The following day the cells were dosed with compound (diluted from 10mM stock in DMSO using DMEM (without phenol red, 10% FCS, 1% L-glutamine, 1% penicillin/streptomycin). Untreated control wells and wells containing a compound known to give 100% inhibition of BrdU incorporation were included on each plate. After 48 hours in the presence / absence of test compound the ability of the cells to incorporate BrdU over a 2 hour labelling period was determined using a Boehringer (Roche) Cell Proliferation BrdU ELISA kit (cat. No. 1 647 229) according to manufacturer's directions. Briefly, 15μl of BrdU labelling reagent (diluted 1:100 in media - DMEM no phenol red, 10% FCS, 1% L-glutamine, 1% penicillin/streptomycin) was added to each well and the plate returned to a humidified (+5% CO₂) 37°C incubator for 2 hours. After 2 hours the labelling reagent was removed by decanting and tapping the plate on a paper towel. FixDenat solution (50μl per well) was added and the plates incubated at room temperature for 45mins with shaking. The FixDenat solution was removed by decanting and tapping the inverted plate on a paper towel. The plate was then washed once with phosphate buffered saline (PBS) and 100μl /well of Anti-BrdU-POD antibody solution (diluted 1:100 in antibody dilution buffer) added. The plate was then incubated at room temperature with shaking for 90min. Unbound Anti-BrdU-POD antibody was removed by decanting and washing the plate 5 times with PBS before being blotted dry. TMB substrate solution was added (100μl/well) and incubated for approximately 10 minutes at room temperature with shaking until a colour change was apparent. The optical density of the wells was then

determined at 690nm wavelength using a TiterTek Multiscan plate reader. The values
from compound treated, untreated and 100% inhibition controls were used to determine
the dilution range of a test compound that gave 50% inhibition of BrdU incorporation.
Compound 18 in Table 1 was effective in this test at 2.47μM

5  **(c) In Vitro cell cycle analysis assay**

This assay determines the ability of a test compound to arrest cells in specific
phases of the cell cycle. Many different mammalian cell lines could be used in this assay
and MCF7 cells are included here as an example. MCF-7 cells were seeded at 3 x 10^5
cells per T25 flask (Costar) in 5 ml DMEM (no phenol red 10% FCS, 1% L-glutamine
1% penicillin / streptomycin). Flasks were then incubated overnight in a humidified
37°C incubator with 5% CO₂. The following day 1ml of DMEM (no phenol red 10%
FCS, 1% L-glutamine 1% penicillin / streptomycin) carrying the appropriate
concentration of test compound solubilised in DMSO was added to the flask. A no
compound control treatments was also included (0.5% DMSO). The cells were then
incubated for a defined time (usually 24 hours) with compound. After this time the
media was aspirated from the cells and they were washed with 5ml of prewarmed (37°C)
sterile PBSA, then detached from the flask by brief incubation with trypsin and followed
by resuspension in 10ml of 1% Bovine Serum Albumin (BSA, Sigma-Aldrich Co.) in
sterile PBSA. The samples were then centrifuged at 2200rpm for 10 min. The
supernatant was aspirated and the cell pellet was resuspended in 200μl of 0.1% (w/v)
Tris sodium citrate, 0.0564% (w/v) NaCl, 0.03% (v/v) Nonidet NP40, [pH 7.6].
Propidium Iodide (Sigma Aldrich Co.) was added to 40μg/ml and RNAase A (Sigma
Aldrich Co.) to 100μg/ml. The cells were then incubated at 37°C for 30 minutes. The
samples were centrifuged at 2200rpm for 10 min, the supernatant removed and the
remaining pellet (nuclei) resuspended in 200μl of sterile PBSA. Each sample was then
syringed 10 times using 21 gauge needle. The samples were then transferred to LPS
tubes and DNA content per cell analysed by Fluorescence activated cell sorting (FACS)
using a FACScan flow cytometer (Becton Dickinson). Typically 25000 events were
counted and recorded using CellQuest v1.1 software (Verity Software). Cell cycle
distribution of the population was calculated using Modfit software (Verity Software)
and expressed as percentage of cells in G0/G1, S and G2/M phases of the cell cycle.
Treating MCF7 cells with 12.76μM Compound 18 in Table 1 for 24 hours produced the following changes in cell cycle distribution:
