2-PHENYL-BENZIMIDAZOL AND 2-PHENYL-IMIDAZO-4,51-PYRIDINE DERIVATIVES AS CHECKPOINT KINASE CDS1 (CHK2) INHIBITORS FOR THE TREATMENT OF CANCER

Field of the Invention

The present invention relates to substituted benzimidazole and imidazo-[4,5]-pyridine compounds, compositions containing them, and methods of using them.

Background of the Invention

The maintenance of an intact genome is of crucial importance to every organism. The individual cell in a multicellular eukaryotic organism possesses sophisticated and intricate mechanisms to properly respond to DNA damage. Such mechanisms repair damaged DNA or trigger programmed cell death (apoptosis). In response to DNA damage, checkpoint kinases are thought to be intimately involved in these processes. These kinases are activated by upstream proteins, such as ATM (ataxia-telangiectasia mutated) and ATR (ataxia-telangiectasia mutated and rad3-related), and in turn trigger cell cycle arrest by inhibition of proteins such as Cdc25A or Cdc25C. The checkpoint kinases may also modulate the activity of other proteins that are thought to be involved in DNA repair and programmed cell death. Examples of such proteins are BRCA1 and p53.

Cancer cells are often deficient in the mechanisms responsible for maintaining an intact genome. In particular, they have often lost proper p53 function, which generally correlates with the progression of a tumor to a more aggressive state, such as the progression from a preinvasive to invasive stage of colon cancer, or from a low grade to a high grade astrocytoma. Between 30% and 70% of all subtypes of tumors have a point mutation in one of the two p53 gene copies and have lost the other allele. P53-deficient cells are generally more resistant to radiation. It is thought that the lack of initiation of programmed cell death in cancer cells may render such cells less sensitive to DNA-damaging cancer treatments. The transcription factor p53 is of importance not only for the initiation of programmed cell death, but also in cell cycle arrest. Loss of p53 function may therefore leave cancer cells with limited protection against insult to the genome. Further disruption of DNA damage repair and cell cycle arrest by inhibition of kinases such as Cds1 could then render cancer cells unable to survive after DNA damage. Therefore inhibition of Cds1 could, by removing the remaining components of DNA damage repair, render the cancer cells more susceptible to treatments such as chemical DNA-damaging agents or ionizing radiation.

Normal cells, on the other hand, have an intact p53 system, and will often undergo apoptosis in response to DNA-damaging treatments at a much lower dose than that required to kill cancer cells. Therefore, in such situations, normal cells will be at a disadvantage compared to cancer cells, and cancer treatments often have to be discontinued due to serious side effects caused by loss of normal cells before the cancer has been eradicated. Inhibition of Cds1, which would prevent this kinase from phosphorylating and thereby stabilizing p53, could therefore protect normal cells from the effects of ionizing radiation or DNA-damaging chemotherapeutics while still allowing these agents to be effective against p53-deficient cancer cells. This would have the effect of increasing the therapeutic potential of these agents. This view is supported by studies of mice deficient in Cds1 (See: Hirao, A. et al. Mol. Cell. Biol. 2002, 22(18):6521–6532; Takai, H. et al. EMBO J. 2002, 21(19):5195–5205; WO 01/98465 A1 Chugai Seiyaku Kabushiki Kaisha, December 27, 2001). These animals showed increased resistance to the apoptosis caused by ionizing
radiation over their wild-type counterparts. For example, it was shown that these animals were protected from apoptosis of intestinal cells, hair follicle cells, cells of the CNS, and thymus cells relative to their wild-type counterparts when treated with ionizing radiation. Cds1 knockout animals also showed increased survival when exposed to ionizing radiation. It is therefore logical to assume that chemical inhibitors of Cds1 would have therapeutic potential in the protection of patients from the deleterious side effects of radiation or DNA-damaging chemotherapeutics.

Additional examples of cell cycle checkpoint modulators in development include UCN-01 (CAS 112953-11-4), UCN-02, KW-2401, NSC-638850 (Kyowa Hakko/National Cancer Institute) and SB-218078 (CAS 135897-06-2) (SmithKline Beecham).

In one aspect, the invention provides a method for treating a subject suffering from cancer, said method comprising administering to said subject a therapeutically effective amount of a pharmaceutical composition comprising a compound of formula (I). According to one aspect, the cancer is p-53 deficient.

In another aspect, the invention provides a method for treating a subject suffering from a p53-deficient tumor, said method comprising (a) administering to said subject a therapeutically effective amount of a pharmaceutical composition comprising a compound of formula (I) and (b) damaging the DNA of said subject, for example, by administration of a DNA-damaging treatment or agent, such as ionizing radiation or a chemical agent that causes DNA damage. In one aspect, the DNA damaging treatment is provided such that administration of the compound of formula (I) provides effective serum levels of the compound of formula (I) during the treatment and 12 hours to 5 days thereafter, for example, 1-2 days thereafter. In a further aspect, the method of
treatment further includes administration of one or more additional anti-cancer agents, to provide in total three or four (or more) agents, to be administered in an effective anti-cancer amount. Multiple or combination therapies may allow use of lower amounts of one or more of the individual agents, when compared with monotherapy, and thereby reducing the incidence or degree of adverse effects.

Examples of such DNA-damaging chemical agents are compounds that cause DNA strand breaks directly such as bleomycin. DNA damage may also be caused by alkylating agents such as hexamethylamine, busulfan, carboplatin, carmustine, cisplatinum, cyclophosphamide, dacarbazine, ifosfamide, lomustine, mechlorethamine, melphalan, procarbazine, streptozocin or thiopeta, or combinations thereof. DNA damage may also be caused indirectly by topoisomerase inhibitors such as etoposide, irinotecan, teniposide, topotecan, and doxorubicin or by antimetabolites such as cladribine, cytarabine, floxuridine, 5-fluorouracil, gemcitabine, hydroxyurea, mercaptopurine, methotrexate, pentostatin, thioguanine, and triemtrelxate. Enhancement of DNA damaging effects and improved therapeutic responses can be obtained by combining anticancer agents such as those exemplified above.

A third aspect of the invention provides the use, or the use for the manufacture of a medicament, of a disclosed compound for treating a tumor, in particular, a p53 deficient tumor, and more in particular, a tumor selected from lung, prostate, colon, brain, head and neck, and breast. Other tumors include tumors of the stomach, liver, and ovary. A p-53 deficient tumor is a tumor wherein the functions mediated by p53 are lacking or suppressed due to genetic mutations in the gene encoding p53 or through deficiencies or disregulation of proteins that modulate p53 expression levels and function. Examples of such proteins are MDM2 and p14(ARF). A further aspect of the invention includes the treatment of a late-stage, e.g., stage 3 or stage 4, tumor.

The invention also features anti-cancer pharmaceutical compositions comprising as active ingredient an effective amount of a disclosed compound of formula (I), and a pharmaceutically acceptable carrier. The active ingredient can be formulated in any manner suitable for the particular tumor, including
aerosol, oral, injectable and topical formulations, and time-release formulations thereof.

Additional features and advantages of the invention will become apparent from the detailed description and examples below, and the appended claims.

Alkoxy includes methoxy, ethoxy, propoxy, isopropoxy, butoxy, t-butoxy, pentoxy and so on. "Aminoalkyl", "thioalkyl", and "sulfonylalkyl" are analogous to alkoxy, replacing the terminal oxygen atom of alkoxy with, respectively, NH (or NR), S, and SO₂. Heteroalkyl includes alkoxy, aminoalkyl, thioalkyl, and so on.

"Aryl" includes phenyl, naphthyl, biphenylyl, tetrahydronaphthyl, and so on, any of which may be optionally substituted. Aryl also includes arylalkyl groups such as benzyl, phenethyl, and phenylpropyl. Aryl includes a ring...
system containing an optionally substituted 6-membered carbocyclic aromatic ring, said system may be bicyclic, bridge, and/or fused. The system may include rings that are aromatic, or partially or completely saturated. Examples of ring systems include indenyl, pentalenyl, 1-4-dihydronaphthyl, indanyl, benzimidazolyl, benzothiophenyl, indolyl, benzofuranyl, isoquinolinyl, and so on.

"Heterocycyl" includes optionally substituted aromatic and nonaromatic rings having carbon atoms and at least one heteroatom (O, S, N) or heteroatom moiety (SO_2, CO, CONH, COO) in the ring. Unless otherwise indicated, a heterocyclic radical may have a valence connecting it to the rest of the molecule through a carbon atom, such as 3-furyl or 2-imidazolyl, or through a heteroatom, such as N-piperidyl or 1-pyrazolyl. Preferably a monocyclic heterocyclyl has between 4 and 7 ring atoms, or between 5 and 6 ring atoms; there may be between 1 and 5 heteroatoms or heteroatom moieties in the ring, and preferably between 1 and 3. A heterocyclyl may be saturated, unsaturated, aromatic (e.g., heteroaryl), nonaromatic, or fused.

Heterocyclyl also includes fused, e.g., bicyclic, rings, such as those optionally condensed with an optionally substituted carbocyclic or heterocyclic five- or six-membered aromatic ring. For example, "heteroaryl" includes an optionally substituted six-membered heteroaromatic ring containing 1, 2 or 3 nitrogen atoms condensed with an optionally substituted five- or six-membered carbocyclic or heterocyclic aromatic ring. Said heterocyclic five- or six-membered aromatic ring condensed with the said five- or six-membered aromatic ring may contain 1, 2 or 3 nitrogen atoms where it is a six-membered ring, or 1, 2 or 3 heteroatoms selected from oxygen, nitrogen and sulfur where it is a five-membered ring.

"Halo" or "halogen" includes fluoro, chloro, bromo, and iodo, and preferably chloro or bromo as a substituent.

"Alkanediyl" or "alkylene" represents straight or branched chain optionally substituted bivalent alkane radicals such as, for example, methylene, ethylene, propylene, butylene, pentylenne or hexylene.

"Alkenediyl" represents, analogous to the above, straight or branched chain optionally substituted bivalent alkene radicals such as, for example, propylene, butylene, pentylene or hexylene. In such radicals, the carbon atom linking a nitrogen preferably should not be unsaturated.

"Aroyl" refers to a carbonyl moiety attached to an optionally substituted aryl or heteroaryl group, wherein aryl and heteroaryl have the definitions provided above. In particular, benzoyl is phenylcarbonyl.

As defined herein, two radicals, together with the atom(s) to which they are attached may form an optionally substituted 4- to 7-, 5- to 7-, or a 5- to 6-membered ring carbocyclic or heterocyclic ring, which ring may be saturated, unsaturated or aromatic. Said rings may be as defined above in the Summary of the Invention section. Particular examples of such rings are as follows in the next section.

"Pharmaceutically acceptable salts, esters, and amides" include carboxylate salts (e.g., C_{1-8} alkyl, C_{3-8} cycloalkyl, aryl, C_{2-10} heteroaryl, or C_{2-10} non-aromatic heterocyclic) amino acid addition salts, esters, and amides that are within a reasonable benefit/risk ratio, pharmacologically effective and suitable for contact with the tissues of patients without undue toxicity, irritation, or allergic response. Representative salts include hydrobromide, hydrochloride, sulfate, bisulfate, nitrate, acetate, oxalate, valerate, olate,

These may include alkali metal and alkali earth cations such as sodium, potassium, calcium, and magnesium, as well as non-toxic ammonium, quaternary ammonium, and amine cations such as tetramethyl ammonium, methylamine, trimethylamine, and ethylamine. See example, S.M. Berge, et al., "Pharmaceutical Salts," J. Pharm. Sci., 1977, 66:1-19, which is incorporated herein by reference.

Representative pharmaceutically acceptable amides of the invention include those derived from ammonia, primary C<sub>1-6</sub> alkyl amines and secondary di (C<sub>1-6</sub> alkyl) amines. Secondary amines include 5- or 6-membered heterocyclic or heteroaromatic ring moieties containing at least one nitrogen atom and optionally between 1 and 2 additional heteroatoms. Representative pharmaceutically acceptable esters of the invention include C<sub>1-7</sub> alkyl, C<sub>5-7</sub> cycloalkyl, phenyl, and phenyl(C<sub>1-6</sub>)alkyl esters. Preferred esters include methyl esters.

"Patient" or "subject" includes mammals such as humans and animals (dogs, cats, horses, rats, rabbits, mice, non-human primates) in need of observation, experiment, treatment or prevention in connection with the relevant disease or condition. Preferably, the patient or subject is a human.

"Composition" includes a product comprising the specified ingredients in the specified amounts as well as any product that results directly or indirectly from combinations of the specified ingredients in the specified amounts.

"Therapeutically effective amount" or "effective amount" means that amount of active compound or pharmaceutical agent that elicits the biological or medicinal response in a tissue system, animal or human that is being sought by a researcher, veterinarian, medical doctor or other clinician, which includes alleviation of the symptoms of the condition or disorder being treated.

Concerning the various radicals in this disclosure and in the claims, three general remarks are made. The first remark concerns valency. As with all hydrocarbon radicals, whether saturated, unsaturated or aromatic, and whether or not cyclic, straight chain, or branched, and also similarly with all
heterocyclic radicals, each radical includes substituted radicals of that type and
monovalent, bivalent, and multivalent radicals as indicated by the context of the
claims. The context will indicate that the substituent is an alkylene or
hydrocarbon radical with at least two hydrogen atoms removed (bivalent) or
more hydrogen atoms removed (multivalent). An example of a bivalent radical
linking two parts of the molecule is Z in formula (I), which links X and A.
Second, radicals or structure fragments as defined herein are
understood to include substituted radicals or structure fragments. Hydrocarbys
include monovalent radicals containing carbon and hydrogen such as alkyl,
alkenyl, alkynyl, cycloalkyl, and cycloalkenyl (whether aromatic or unsaturated),
as well as corresponding divalent radicals such as alkylene, alkenylene,
phenylene, and so on. Heterocarbyls include monovalent and divalent radicals
containing carbon, hydrogen, and at least one heteroatom. Examples of
monovalent heterocarbyls include acyl, acyloxy, alkoxyacyl, heterocyclcyl,
heteroaryl, aroyl, benzoyl, dialkylamino, hydroxyalkyl, and so on. Using "alkyl"
as an example, "alkyl" should be understood to include substituted alkyl having
one or more substitutions, such as between 1 and 5, 1 and 3, or 2 and 4
substituents. The substituents may be the same (dihydroxy, dimethyl), similar
(chlorofluoro), or different (chlorobenzyl- or aminomethyl-substituted).
Examples of substituted alkyl include haloalkyl (such as fluoromethyl,
chloromethyl, difluoromethyl, perchloromethyl, 2-bromoethyl, perfluoromethyl,
and 3-iodocyclopentyl), hydroxyalkyl (such as hydroxymethyl, hydroxyethyl, 2-
hydroxypropyl, aminooalkyl (such as aminomethyl, 2-aminoethyl, 3-aminopropyl,
and 2-aminopropyl), nitroalkyl, alkylalkyl, and so on. A di(C 1-5 alkyl)amino
group includes independently selected alkyl groups, to form, for example,
methylpropylamino and isopropylmethylamino; in addition dialkylamino groups
having two of the same alkyl group such as dimethyl amino or diethylamino.
Third, only stable compounds are intended. For example, where there
is an NR'R" group, and R can be an alkenyl group, the double bond is at least
one carbon removed from the nitrogen to avoid enamine formation. Similarly,
where a dashed line is an optional sp² bond, if it is absent, the appropriate
hydrogen atom(s) is (are) included.
Compounds of the invention are further described in the next section.
B. Compounds

Related Compounds

The invention provides the disclosed compounds and closely related, pharmaceutically acceptable forms of the disclosed compounds, such as salts, esters, amides, acids, hydrates or solvated forms thereof; masked or protected forms; and racemic mixtures, or enantiomerically or optically pure forms. Related compounds also include compounds of the invention that have been modified to be detectable, e.g., isotopically labelled with \(^{11}\)C, or \(^{18}\)F for use as a molecular probe in positron emission tomography (PET) or single-photon emission computed tomography (SPECT).

The invention also includes disclosed compounds having one or more functional groups (e.g., hydroxyl, amino, or carboxyl) masked by a protecting group. See, e.g., Greene and Wuts, Protective Groups in Organic Synthesis, 3rd ed., (1999) John Wiley & Sons, NY. Some of these masked or protected compounds are pharmaceutically acceptable; others will be useful as intermediates. Synthetic intermediates and processes disclosed herein, and minor modifications thereof, are also within the scope of the invention.

C. Synthetic Methods

The invention provides methods of making the disclosed compounds according to traditional organic synthetic methods as well as matrix or combinatorial synthetic methods. Schemes 1 through 9 describe suggested synthetic routes. Using these Schemes, the guidelines below, and the examples, a person of skill in the art may develop analogous or similar methods for a given compound that are within the invention.

One skilled in the art will recognize that synthesis of the compounds of the present invention may be effected by purchasing an intermediate or protected intermediate compounds described in any of the schemes disclosed herein. One skilled in the art will further recognize that during any of the processes for preparation of the compounds in the present invention, it may be necessary and/or desirable to protect sensitive or reactive groups on any of the
molecules concerned. This may be achieved by means of conventional protecting groups, such as those described in "Protective Groups in Organic Synthesis", John Wiley & Sons, 1991. These protecting groups may be removed at a convenient stage using methods known from the art.

Examples of the described synthetic routes include Synthetic Examples 1 through 78. Compounds analogous to the target compounds of these examples can be, and in many cases, have been, made according to similar routes. The disclosed compounds are useful in basic research and as pharmaceutical agents as described in the next section.

Broadly, compounds of formula I may be made according to Scheme 1. Aldehyde (III) can be condensed with diamine (II) in the presence of an oxidizing agent such as Na$_2$S$_2$O$_5$ to provide benzimidazoles (I). This reaction takes place in a solvent, such as DMA or DMF, with the application of heat. Better yields might be obtained where the reaction is heated to a temperature of from 80 °C to 100 °C. However in the case that Z is a carbonyl, better yields are obtained at a reaction temperature of 60 °C. Compounds where Z contains an alcohol form a dimer in this reaction, which must be hydrolyzed in the presence of water and an acid at elevated temperatures. Improved yields for compounds where Z is an alcohol may be obtained as described below for Scheme 6.

![Scheme 1](attachment://Scheme_1.png)

Schemes 2, 3, 4 and 5 show the formation of various aldehyde (III) subtypes. Referring to Scheme 2, a ketone (IV) may be protected to form, for example, a dioxolane. Lithium halogen exchange of the bromide with a suitable alkyl lithium reagent such as n-BuLi, followed by a DMF quench will produce aldehyde (IIIa). Other protecting groups amenable to lithium halogen
exchange chemistry may also be employed. In this regard, reference is made
Deprotection of the ketone protecting group, in this case with a suitable acid
such as perchloric acid, affords aldehyde (IIIb). Other functional groups in A or
in R_c that are sensitive to chemistry utilizing butyl lithium should be protected.
For example, a carbonyl group should be protected as the ketal as described
for Z.

\]

Referring to Scheme 3, anilines (V) may be halogenated in the para
position by treatment with a brominating agent such as N-bromosuccinimide.
Lithium halogen exchange as described above followed by a DMF quench can
be used to produce aldehydes of type (IIIc). Groups in A or in R_c that are
sensitive to chemistry utilizing butyl lithium should be protected. For example,
a carbonyl group should be protected as the ketal as described for Z. In one
alternative to Scheme 3, a phenyl alkyl amine may be cross-coupled with 4-
bromobenzaldehyde in the presence of a palladium catalyst to produce
aldehyde (IIIc).

Referring to Scheme 4, an aldehyde/ketone (VI) undergoes a Grignard
reaction with an appropriate Grignard reagent (VII) that contains a masked
aldehyde to produce bicyclic alcohol (VIII). Where X_1 is hydrogen, alcohol (VII)
is oxidized and deprotected to the aldehyde (IIIb). Where there are groups in A
or $R_c$ that are sensitive to oxidation, mild oxidation conditions should be employed such as TEMPO or PDC or an appropriate protecting group should be employed. Where $X_1$ is alkyl, alcohol (VII) is exposed to perchloric acid, allowing for deprotection of the aldehyde in addition to dehydration of the alcohol to form aldehyde (IIIc). Hydrogenation of the double bond in compounds of formula (I) derived from (IIIc) can lead to alternative embodiments of formula (I) in which $Z$ is $>CR_dR_d$. Where there are groups in $A$ or $R_c$ that are sensitive to oxidation, mild deprotection conditions should be employed conc. HCl in THF. Where $X_1$ is hydrogen, alcohol (VII) is exposed to a protic acid which deprotects to form aldehyde (IIIC). Where there are groups in $A$ or $R_c$ that are sensitive to oxidizing conditions, non-oxidizing acids should be used for the deprotection such as HCl.

Scheme 4

Referring to Scheme 5, substituted amine (X) is sulfonylated with a formylated benzene sulfonyl chloride derivative (IX) to produce aldehyde (IIIIf). In the case that $X_1$, $R_c$ or $A$ contains a primary alcohol then this alcohol should be protected with an acid sensitive protecting group, such as a silyl ether. The bicyclic A fused sulfonamides may be produced in Scheme 5 where the depicted cyclic substituted amine is replaced with an amine of the formula.
Referring to Scheme 6, compounds of formula (Xlb) can be obtained by reducing compounds of formula (Xla) with NaBH₄, LiBH₄, Na(OAc)₃BH, DIBAL-H or other reducing agent. Compounds of formula (Xlb) may be further reduced with reducing agents, including NaBH₄, triethylsilylethride, TES-Cl or TMS-Cl to obtain compounds of formula (Xlc). Compounds of formula (Xlb) may be alkylated to form compounds of formula (Xld) by various methods. In the depicted method, the alcohol is converted to a good leaving group, such as a chloride, using either HCl or SOCl₂, and the resulting benzyl chloride may be displaced with a variety of alcohols to produce the corresponding ether (Xld).

In another method, a base, such as NaH, is used with an alkylating agent, such as Mel, to form a methyl ether. The desired R₆ may be obtained with various alkylating agents. Compounds of formula (Xlb) may be aminated to form compounds of formula (Xle) by first forming the chloride with chlorinating agents such as SOCl₂ or HCl and subsequently displacing the chloride with the appropriate amine.
Referring to Scheme 7, compounds of formula (Xlg) can be obtained by nucleophilic addition of an appropriate Grignard or lithium reagent to compound (Xla). The resulting tertiary alcohol may then be converted to ethers or amines of type (Xlh) or (Xlj) using the methods described in Scheme 6. Compounds of formula (Xlg) can also be converted into analogs of formula (IIIId) in Scheme 4 by treatment with perchloric acid. The resulting double bond can be hydrogenated to access alternative embodiments of formula (I) in which Z is >CRdRd.
Referring to Scheme 8, the carboxylic acid of formula (XII) can be converted to an amide by treatment with 1,1'-carbonyldiimidazole (CDI), or other similar activating agent, followed by a nucleophilic amine to provide compounds of formula (XIII). Standard peptide coupling conditions known to one skilled in the art are also applicable.

Compounds of general formula (XIX) can be synthesized using the methods outlined in Scheme 9. Treatment of pyridine (XIV) with an ammonium equivalent such as (NH₄)₂CO₃ provides 2-aminopyridine (XV). Removal of the methyl group in (XV) with hydrobromic acid and acetic acid, followed by conversion to the bromide using a nucleophilic bromide source such as (C₄H₉)₄N⁺Br⁻, in the presence of P₂O₅, gives compound (XVI). Treatment of the bromide with a metallic cyanide such as CuCN then results in the formation of compound (XVII). Reduction of the nitro group of (XVII) using H₂ and Pd or other reducing agent, followed by condensation with an aryl aldehyde of type (III) in the presence of an oxidizing agent such as Na₂S₂O₅ provides
imidazopyridines of general formula (XVIII). The cyano group of (XVIII) can then be converted to an amide of formula (XIX) by hydrolysis with BF₃ in acetic acid.

D. Formulation and Administration

The present compounds inhibit the checkpoint modulator Cds1 and therefore are useful as a medicine especially in methods for treating patients suffering from disorders or conditions that are modulated or regulated by Cds1, such as cancer.

The invention features a method for treating a subject with cancer, said method comprising administering to the subject a therapeutically effective amount of a pharmaceutical composition comprising a compound of the invention. The invention also provides a method for inhibiting Cds1 activity in a subject, wherein the method comprises administering to the subject a therapeutically effective amount of a pharmaceutical composition comprising a compound of the invention.

The compounds of the present invention may be formulated into various pharmaceutical forms for administration purposes. To prepare these pharmaceutical compositions, an effective amount of a particular compound, in
base or acid addition salt form, as the active ingredient is intimately mixed with
a pharmaceutically acceptable carrier.

A carrier may take a wide variety of forms depending on the form of
preparation desired for administration. These pharmaceutical compositions
are desirably in unitary dosage form suitable, preferably, for oral
administration, intravenous injection or parenteral injection. For example, in
preparing the compositions in oral dosage form, any of the usual
pharmaceutical media may be employed. These include water, glycols, oils,
alcohols and the like in the case of oral liquid preparations such as
suspensions, syrups, elixirs and solutions; or solid carriers such as starches,
sugars, kaolin, lubricants, binders, disintegrating agents and the like in the
case of powders, pills, capsules and tablets. In view of their ease in
administration, tablets and capsules represent the most advantageous oral
dosage unit form, in which case solid pharmaceutical carriers are generally
employed. For parenteral compositions, the carrier will usually comprise sterile
water, at least in large part, though other ingredients, for example, to aid
solubility, may be included. Injectable solutions, for example, may be prepared
in which the carrier comprises saline solution, glucose solution or a mixture of
saline and glucose solution. Injectable suspensions may also be prepared in
which case appropriate liquid carriers, suspending agents and the like may be
employed. In the compositions suitable for percutaneous administration, the
carrier optionally comprises a penetration enhancing agent and/or a suitable
wetting agent, optionally combined with suitable additives of any nature in
minor proportions, which additives do not cause a significant deleterious effect
to the skin. Such additives may facilitate the administration to the skin and/or
may be helpful for preparing the desired compositions. These compositions
may be administered in various ways, e.g., as a transdermal patch, as a spot-
on, as an ointment. Acid addition salts of the compounds of formula I, due to
their increased water solubility over the corresponding base form, are more
suitable in the preparation of aqueous compositions.

It is especially advantageous to formulate the aforementioned
pharmaceutical compositions in dosage unit form for ease of administration
and uniformity of dosage. Dosage unit form as used in the specification herein
refers to physically discrete units suitable as unitary dosages, each unit containing a predetermined quantity of active ingredient calculated to produce the desired therapeutic effect in association with the required pharmaceutical carrier. Examples of such dosage unit forms are tablets (including scored or coated tablets), capsules, pills, powder packets, wafers, injectable solutions or suspensions, teaspoonfuls, tablespoonfuls and the like, and segregated multiples thereof.

Pharmaceutically acceptable acid addition salts include the therapeutically active non-toxic acid addition salt forms that the disclosed compounds are able to form. The latter can conveniently be obtained by treating the base form with an appropriate acid. Appropriate acids comprise, for example, inorganic acids such as hydrohalic acids, e.g. hydrochloric or hydrobromic acid; sulfuric; nitric; phosphoric and the like acids; or organic acids such as, for example, acetic, propanoic, hydroxyacetic, lactic, pyruvic, oxalic, malonic, succinic, maleic, fumaric, malic, tartaric, citric, methanesulfonic, ethanesulfonic, benzenesulfonic; p-toluenesulfonic, cyclamic, salicylic, p-aminosalicylic, palmoic and the like acids. The term addition salt also comprises the solvates that the disclosed compounds, as well as the salts thereof, are able to form. Such solvates are for example hydrates, alcohohlates and the like. Conversely the salt form can be converted by treatment with alkali into the free base form.

"Stereoisomeric forms" defines all the possible isomeric forms that the compounds of formula (I) may possess. Unless otherwise mentioned or indicated, the chemical designation of compounds denotes the mixture of all possible stereochemically isomeric forms, said mixtures containing all diastereomers and enantiomers of the basic molecular structure. More in particular, stereogenic centers may have the (R)- or (S)-configuration; substituents on bivalent cyclic saturated radicals may have either the cis- or trans-configuration. The invention encompasses stereochemically isomeric forms including diastereoisomers, as well as mixtures thereof in any proportion of the disclosed compounds. The disclosed compounds may also exist in their tautomeric forms. Such forms although not explicitly indicated in the above and following formulae are intended to be included within the scope of the
present invention. For example, the present invention includes

as well as

5 2-[4-(4-Chloro-benzoyl]-3H-benzoimidazole-5-carboxylic acid amide.

Those of skill in the treatment of disorders or conditions mediated by the Cds1 enzyme could easily determine the effective daily amount from the test results presented hereinafter and other information. In general it is contemplated that a therapeutically effective dose would be from 0.001 mg/kg to 100 mg/kg body weight, more preferably from 1 mg/kg to 50 mg/kg body weight. It may be appropriate to administer the therapeutically effective dose as two, three, four or more sub-doses at appropriate intervals throughout the day. Said sub-doses may be formulated as unit dosage forms, for example, containing 1 mg to 2000 mg, and in particular 10 to 500 mg of active ingredient per unit dosage form. Examples include 10 mg, 25 mg, 50 mg, 100 mg, 150 mg, 250 mg, and 500 mg dosage forms. Compounds of the invention may also be prepared in time-release or subcutaneous or transdermal patch formulations. Disclosed compound may also be formulated as a spray or other topical or inhalable formulations.

The exact dosage and frequency of administration depends on the particular compound of formula (I) used, the particular condition being treated, the severity of the condition being treated, the age, weight and general physical condition of the particular patient as well as other medication the patient may be taking, as is well known to those skilled in the art. Furthermore, it is evident that said effective daily amount may be lowered or increased depending on the response of the treated patient and/or depending on the evaluation of the
physician prescribing the compounds of the instant invention. The effective
daily amount ranges mentioned herein are therefore only guidelines.

The next section includes detailed information relating to the use of the
disclosed compounds.

**Determination of compound inhibition of human Cds1 activity**

For the determination of human Cds1 activity in the presence of Cds1 inhibitory compounds, such compounds were incubated in an aqueous mixture at pH 7.4 containing 50 mM HEPES, 100 mM NaCl, 10 mM MgCl<sub>2</sub>, 5 nM recombinant human Cds1, 10 μM synthetic peptide substrate SGLYRSPSMPENLNRPR having an N-terminal biotin, 1 μM adenosine triphosphate, 50 μCi/mL of [γ<sup>32</sup>P] adenosine triphosphate, and a protease inhibitor mixture. The reaction mixtures were incubated at 37 °C for 3 h. The peptide substrate was captured from the reaction mixture by incubating the reaction mixture with streptavidin conjugated to agarose beads and 50 mM adenosine triphosphate. The agarose beads were washed repeatedly with a 0.1% solution of Tween®-20 in phosphate-buffered saline, pH 7.4. Enzyme activity at different Cds1 inhibitory compound concentrations was determined by measuring the amount of radioactive phosphate bound to the substrate peptide by scintillation counting. Results are expressed as IC<sub>50</sub> in Table 1 below.

Example 80

**Determination of the effect of Cds1 inhibitory compounds on radiation-induced apoptosis in isolated primary cells**

Spleen cells were isolated from C57/BL6 mice as follows: spleens were disrupted by grinding between two frosted glass slides, and cells were passed through a cell strainer. Erythrocytes were lysed by incubation in ammonium chloride solution followed by careful washing of cells in isotonic medium. The spleen cells were plated in 60 mm petri dishes at 5 × 10⁶ cells/mL in RPMI medium containing 10% fetal calf serum and Cds1 inhibitor. One hour after plating of cells with compound, the cells were dosed with 0.5–1 Gy from a ¹³⁷Cs γ-radiation source. Determination of apoptotic cells by Annexin V staining was performed using the Annexin V-FITC Apoptosis Detection Kit™ (Cat# PF032 Oncogene Research Products) according to the manufacturer’s instructions. Briefly, 6–24 h after irradiation, the cells were washed with buffered isotonic salt solution and suspended at 1 × 10⁶ cells/mL in binding buffer (10 mM HEPES pH 7.4, 150 mM NaCl, 2.5 mM CaCl₂, 1 mM MgCl₂, 4% bovine serum albumin) containing 80 ng/mL Annexin V labelled with FITC and 0.4 μg/mL anti-B220 antibody labelled with allophycocyanin. The cells were then pelleted and resuspended in binding buffer containing 0.6 μg/mL propidium iodide. The stained cells were analyzed on a FACS machine (Fluorescence Activated Cell Sorter™, Becton Dickinson). The fraction of viable, non-apoptotic cells was determined by quantifying the number of cells that did not stain with propidium iodide or Annexin V versus the total number of cells. Fractions of non-apoptotic B-cells or total cells were determined separately based on staining with the B220 antibody mentioned above.
Example 81

**Determination of effect of Cds1 inhibitors on radiation-induced caspase activity in human CD4⁺ T-cells**

Human CD4⁺ T-cells were isolated from the blood of healthy donors as follows. Whole heparinized blood was layered over Ficoll-Paque (Amersham Pharmacia Biotech, Uppsala, Sweden) and centrifuged 20 min at 560g. Mononuclear cells were harvested and subjected to positive selection with anti-human CD4-coated MACS MicroBeads (Miltenyi, Auburn, CA). Purified CD4⁺ T-cells were transferred to growth medium (RPMI with 10% fetal calf serum, 50%IU/mL penicillin and 50 μg/mL streptomycin). The cells were dispensed to wells of 96-well tissue culture plates at 200,000 cells/well. Either a Cds1 inhibitory compound in DMSO or the same volume of vehicle was added to each well. The reaction mixtures were incubated at 37 °C for 1 h, exposed to 10 Gy of γ-radiation, and then incubated for 24 h. The CD4⁺ T-cells were harvested by centrifugation and lysed to release caspase-3. Caspase-3 and caspase-7 specific fluorogenic peptide substrate Acetyl-Asp-Glu-Val-Asp-(7-amino-4-methyl-coumarin) was added to each sample (final concentration = 100 μM). Three hours after the addition of peptide, the caspase activity of each sample was determined fluorometrically using a Millipore Cytofluor fluorescent plate reader (λ_ex = 360 nm, λ_em = 460 nm).

Example 82

**Determination of the effect of Cds1 inhibitory compounds on radiation-induced apoptosis in human CD4⁺ T-cells**

Human CD4⁺ T-cells were isolated from the blood of healthy donors and cultured as described in Example 54. The cells were dispensed to wells of 96-well tissue culture plates at 200,000 cells/well. Either a Cds1 inhibitory compound in DMSO or the same volume of vehicle was added to each well. The reaction mixtures were incubated at 37 °C for 1 h, exposed to 10 Gy of γ-radiation, and then incubated for 24 h. Determination of apoptotic cells by Annexin V staining was performed as described in Example 53.
Example 83

**Determination of the effect of Cds1 inhibitory compounds on radiation-induced apoptosis in splenocytes in vivo**

Female C57/BL mice, 6–8 weeks of age, are dosed by oral gavage or by injection with Cds1 inhibitory compound before and at regular intervals after radiation exposure. One to three hours after first compound dose, the animals are irradiated with γ-rays administered to the whole animal at a dose between 0.5 and 4 Gy. At times between 4 and 24 h after irradiation, the animals are sacrificed, and the tissues of interest are excised. Cell apoptosis is quantified using Annexin V staining as described in Example 53. Apoptosis can be studied in a variety of tissues. In some cases other methods for quantification of apoptosis than the method described in Example 53 may be more appropriate. Thus, apoptosis can also be determined by detection of DNA degradation by TUNEL staining, as described by Darzynkiewicz and Bedner (In *Analysis of Apoptotic Cells by Flow and Laser-Scanning Cytometry*; Reed, J.C., Ed.; Methods of Enzymology, Vol. 322; Academic Press: San Diego, 2000; 18–39). Briefly, cells or tissues are fixed with formaldehyde and permeabilized with ethanol, and DNA ends are then labelled by attaching nucleotide derivatives such as BrdUTP using the enzyme terminal deoxynucleotidyl transferase. DNA ends can then be detected by incubating the cells or tissues with fluorescently-labelled antibodies reactive with BrdU. Quantification can be done by laser scanning cytometry, by visual microscopical examination or by FACS.

INTERNATIONAL SEARCH REPORT

Box II  Observations where certain claims were found unsearable (Continuation of Item 2 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. 
   - Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:
   
   Although claims 49 and 51 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.

2. 
   - Claims Nos.: because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:

3. 
   - Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box III  Observations where unity of invention is lacking (Continuation of Item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. 
   - As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.

2. 
   - As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.

3. 
   - As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:

4. 
   - No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims, it is covered by claims Nos.:

Remark on Protest

- The additional search fees were accompanied by the applicant's protest.
- No protest accompanied the payment of additional search fees.
