Title: INDUCTIVE POWER SUPPLY WITH DEVICE IDENTIFICATION

Abstract: An inductive power supply system (10) to identify remote devices (14) using unique identification frequencies. The system includes an AIPS (12) and a tank circuit (48) capable of inductively providing power to a remote device (14) at different frequencies, and a sensor (16) for sensing the reflected impedance of the remote device at tank circuit (48). The system further includes a plurality of different remote devices (14), each having a unique resonance frequency. In operation, the AIPS (12) is capable of identifying the type of remote device (14) present in the inductive field by applying power to a remote device (14) at a plurality of unique identification frequencies until the remote device (14) establishes resonance in response to one of the identification frequencies. The AIPS (12) includes a controller (40) that recognizes when resonance has been established by evaluating sensor data, which is representative of the reflected impedance of the remote device (14). Once the identity of a remote device is determined, the AIPS (12) may pull operating parameters for the remote device (14) from memory (24) to ensure efficient operation and to assist in recognizing fault conditions.
The present invention relates to inductive power supply systems, and more particularly to an apparatus and method for inductive powering a variety of alternative remote devices.

There is a significant and continually increasing interest in wireless power supply systems, particularly in the field of consumer and business electronics, such as cell phones, music players, personal digital assistants and other remote devices. Wireless power supply systems provide a variety of benefits over conventional wired connections. Most notably, they eliminate the need for various charging cords and the need to repeatedly plug in and unplug electronic devices for recharging, thereby reducing cost and improving ease and convenience of use.

Systems for providing wireless power using the principles of electromagnetic inductive have been available for many years. Conventional systems have met with limited success as a result of practical limitations on pre-existing inductive technology. For example, to provide reasonably efficient operation, conventional inductive systems typically require close and precise alignment between the primary coil and the secondary coil, as well as a high degree of coordinated tuning between the electronics in the inductive power supply and the electronics in the remote device. These problems are complicated by the fact that different remote devices typically operate within different parameters. For example, one cell phone model is likely to have a different set of operating parameters than a different cell phone model, and even greater differences are likely to exist between remote devices of different types, such as a cell phone and a music player.

U.S. Patent 6,825,620 to Kuennen et al discloses an inductive power supply system that has the ability to adjust its operation to correspond with the operating parameters of various loads. U.S. Patent 6,825,620 to Kuennen et al, which is entitled "Inductively
Coupled Ballast Circuit” and was issued on November 30, 2004, is incorporated herein by reference. This inductive power supply system is capable of efficiently powering a wide variety of loads. Although a marked improvement over pre-existing systems, there is, in some applications, a desire for even greater efficiency over a broader range of products using a single inductive power supply system. In some applications, there exists a desire for a single inductive power supply that is capable of making a distinction between different loads, based upon various operating parameters of those loads. In other applications, there also exists a desire for a single inductive power supply system capable of more readily recognizing fault conditions over a broad range of remote devices.

SUMMARY OF THE INVENTION

The present invention provides an inductive power supply system and associated method in which an adaptive inductive power supply ("AIPS") identifies the remote device through reflected impedance, and controls operation as a function of the identity of the remote device. The present invention also provides the AIPS with the ability to assess fault conditions by recognizing when the secondary circuit is operating outside of normal operating conditions for the identified device.

In one embodiment, the present invention includes an AIPS having a controller capable of supplying power to the secondary circuit at various frequencies and a current sensor capable of directly or indirectly sensing the current in the tank circuit. In this embodiment, each remote device or type of remote device includes one or more resonant frequencies that individually or collectively provide a signature that is unique to that device or type of remote device. For example, the identification frequency(ies) may uniquely identify a specific model of cell phone or a specific model of personal digital assistant. The system may also include a look-up table or other data collection containing operating information for
one or more recognizable remote devices. This information can be used to establish operating parameters and recognize fault conditions.

In operation, the AIPS applies a short pulse of power to the secondary circuit at a frequency that is uniquely associated with a specific remote device. If the remote device has a resonant frequency at the frequency of the pulse, the remote device will draw a material amount of current, which will be reflected back into the tank circuit through reflected impedance. The controller will recognize the presence of the remote device when input from the current sensor shows the increased power draw. This permits the AIPS to recognize that a specific remote device is present and to obtain its operating parameters from the look-up table. Once the operating parameters have been retrieved, the AIPS can use the retrieved parameters to more efficiently power the device and to recognize that a fault condition has occurred when actual operating conditions fall outside the retrieved operating parameters.

In some applications, the remote device may inherently include a resonant frequency (or plurality of resonant frequencies) that is sufficiently unique to permit it to function as an identification frequency. In such application, the remote device will operate at resonance when the corresponding identification frequency is applied, thereby uniquely identifying the remote device.

In other applications, the remote device may not inherently have a resonant frequency at a frequency that will uniquely identify the remove device. With remote devices of this nature, the remote device can be provided with an identification capacitor that is selected to provide the remote device with a unique resonant frequency (or pattern of frequencies) that can be identified using an identification ping. In some applications, the main circuitry of the remote device may mask the identification capacitor. Accordingly, in some applications, the remote device may include a load delay circuit that isolates the main circuit of the remote device from the secondary coil and the identification capacitor for a
sufficient period of time to allow resonance to be established by the identification capacitor and reflected back to the tank circuit.

In applications where the number of potential remote devices is large, a plurality of capacitors may be used to provide the remote devices with a plurality of resonant frequencies that collectively provide each remote device with a unique resonant "signature" in response to pings at different frequencies. For example, the use of two different capacitors can be used to provide three separate resonant frequencies—one for each capacitor individually and a third for the combination of the two capacitors. In one embodiment, the presence or absence of resonance at select frequencies can be used as the bits in a binary code that can unique identify a large number of remote devices with only a limited number of frequencies.

In one embodiment, the method generally includes the steps of applying a short pulse of power to the secondary circuit at an identification frequency, waiting a period of time and sensing the current in the tank circuit to determine if a remote device is present that has a resonant frequency at the frequency of the short pulse of power. If so, the remote device is identified and the operating parameters can be pulled from a lookup table or other memory device. If not, the AIPS can move to the next identification frequency and repeat the process. In some applications, a small delay may be implemented between each identification ping to allow the circuit to settle so that residual energy from one identification ping does not impact the remote device's response to the next identification ping. The system may repeatedly cycle through all of the possible identification frequencies until a remote device is positively identified.

In another embodiment, each remote device capable of being powered by an inductive power supply is provided with a capacitor with the same common resonant frequency. The inductive power supply is programmed to send a short power pulse at that
single common resonant frequency. A response from the device, as described above, indicates that the device is capable of receiving power from the power supply.

In another embodiment, each device capable of being powered by an inductive power supply is equipped with a capacitor with a common resonant frequency, and one or more additional capacitors with unique secondary and / or tertiary resonant frequencies. According to this embodiment, the inductive power supply is programmed to send a short power pulse at the single common resonant frequency. When the supply senses a response at that frequency, the inductive power supply sends out additional short pulses at different frequencies, or over a range of frequencies. Depending on the responses at the various frequencies, the power supply is able to distinguish the type of device, and the specific device model.

Once a remote device has been identified, the AIPS can provide power to the remote device in accordance with the operating parameters pulled from memory. Additionally, the AIPS can use information from the lookup table to help identify fault conditions. For example, the lookup table can include minimum and maximum operating frequencies, as well as minimum and maximum current usage. If the current draw on the primary exceeds the maximum current retrieved from the lookup table, the AIPS will recognize a fault condition and take appropriate action, such as powering down the primary.

The present invention provides a simple and effective method and apparatus for identifying remote devices. The lookup table permits the AIPS to retrieve information regarding the remote devices, such as normal operating parameters. This allows the AIPS to more efficiently power the remote device and to more readily identify fault conditions. In applications where a single resonant frequency does not provide a sufficient number of unique identifications, each device may be provided with a pattern of identification frequencies. In applications where a remote device inherently includes a uniquely identifying
resonant frequencies (or frequency pattern), the present invention requires no modification to
the remote device. In applications where a remote device does not include an inherent
uniquely identifying resonant frequency, the remote device may be provide with one or more
identification capacitors that provide the remote device with an identification frequency or an
identification frequency pattern. In another aspect, the present invention provides a set of
standards from which a class of remote devices may be identified by predetermined
identification frequencies. This permits intelligent operation of the AIPS for an essentially
unlimited numbers of remote devices that fit within one of the predetermined classes of
remote devices.

These and other objects, advantages, and features of the invention will be readily understood and appreciated by reference to the detailed description of the current embodiment and the drawings.

DESCRIPTION OF THE CURRENT EMBODIMENT

An inductive power supply system in accordance with an embodiment of the present invention is shown in Fig. 1. The inductive power supply system 10 generally includes an adaptive inductive power supply ("AIPS") 12 and one of a plurality of remote devices 14. The AIPS 12 generally includes a tank circuit 48 with a primary coil 18 (See Fig. 2) capable of inductively transmitting power. The AIPS also includes a controller 20 for selectively controlling the frequency at which power is generated by the primary coil 18, and a sensor 16 capable of sensing reflected impedance from a remote device 14. The AIPS 12 is intended for use with one or more remote devices 14, each of which has a unique resonant frequency or unique pattern of resonant frequencies. In operation, the AIPS 12 applies power to the primary 18 at an identification frequency and then evaluates the reflected impedance of the remote device 14 using the current sensor 16. If the remote device 14 has a resonant frequency at the identification frequency, then the AIPS 12 knows what type of remote device is inductively coupled to AIPS 12 and the AIPS 12 can recover operating parameters from a look-up table or other memory device. The recovered information can be used by the AIPS to provide efficient operation of the remote device and to identify fault conditions.

1. **Adaptive Inductive Power Supply.**

The present invention is suitable for use with a wide variety of adaptive inductive power supplies. As used herein, the term "adaptive inductive power supply" is intended to broadly include any inductive power supply capable of providing power at a plurality of different frequencies. For purposes of disclosure, the present invention is described in connection with a particular AIPS 12. The illustrated AIPS 12 is merely
exemplary, however, and the present invention may be implemented with essentially any AIPS capable of providing inductive power at varying frequencies.

In the illustrated embodiment, the AIPS 12 generally includes a frequency controller 20 and a tank circuit 48. In operation, the frequency controller 20 applies power to the tank circuit 48 to generate a source of electromagnetic inductive power. The frequency controller 20 of the illustrated embodiment generally includes a microcontroller 40, an oscillator 42, a driver 44 and an inverter 46. The microcontroller 40 may be a microcontroller, such as a PIC18LF1320, or a more general purpose microprocessor. The oscillator 42 and driver 44 may be discrete components or they may be incorporated into the microcontroller 40, for example, in the embodiment illustrated in Fig. 2, the oscillator 42 is a module within the microcontroller 40. The frequency controller 20 may also include a low voltage power supply 26 for supplying low voltage power to the microprocessor 40 and the driver 44. In this embodiment, the various components of the frequency controller 20 collectively drive the tank circuit 48 at a frequency dictated by the microcontroller 40. More specifically, the microcontroller 40 sets the timing of the oscillator 42. In certain modes of operation, the microprocessor 40 may establish the operating frequency as a function of input from the current sensor 16. The oscillator 42, in turn, operates the driver 44 at the frequency established by the microcontroller 40. The driver 44 provides the signals necessary to operate the switches 47a-b within the inverter 46. As a result, the inverter 46 provides AC (alternating current) power to the tank circuit 48 from a source of DC (direct current) power 50.

In the illustrated embodiment, the current sensor 16 is a current transformer having its primary coil disposed in the tank circuit 48 and its secondary coil connected to the microcontroller 40. The AIPS may include conditioning circuitry 28 for conditioning the current transformer output before it is supplied to the microcontroller 40. Although the
illustrated embodiment includes a current transformer for sensing the reflected impedance of the remote device, the AIPS 12 may include essentially any alternative type of sensor capable of providing information regarding reflected impedance from the remote device 14. Further, although the current sensor 16 of the illustrated embodiment is located in the tank circuit, the current sensor (or other reflected impedance sensor) can be located in essentially any location where it is capable of providing readings indicative of the presence or absence of resonance in the remote device.

In the illustrated embodiment, the AIPS further includes a lookup table 24 or other memory device capable of storing information relating to the operating parameters of a plurality of remote devices 14. The stored information may be used to permit the AIPS 12 to more efficiently power the remote device 14 and more readily recognize fault conditions. In some applications, the AIPS 12 may be intended for use with a specific set of remote devices 14. In these applications, the lookup table 24 includes the unique resonant frequency (or pattern of frequencies) for each remote device 14, along with the desired collection of associated information, such as maximum and minimum operating frequencies and current usage. The lookup table 24 may, however, include essentially any information that may be useful to the AIPS 12 in operating the remote device 14. For example, in applications where it is desirable to establish wireless communications with the remote device 14, the lookup table 24 may include information regarding the wireless communication protocol of the remote device 14.

The tank circuit 48 generally includes the primary coil 18 and a capacitor 52. The capacitance of capacitor 52 may be selected to balance the impedance of the primary coil 18 at anticipated operating parameters. The tank circuit 48 may be either a series resonant tank circuit (as shown) or a parallel resonant tank circuit (not shown). The present invention may be incorporated into the AIPS shown in U.S. Patent 6,825,620, which as noted above is
incorporated herein by reference. As another example, the present invention may be incorporated into the AIPS shown in U.S. Patent Application Publication US 2004/130916A1 to Baarman, which is entitled "Adapted Inductive Power Supply" and was published on July 8, 2004 (U.S. Serial No. 10/689,499, filed on October 20, 2003), which is also incorporated herein by reference. Further, it may be desirable to use the present invention in connection with an AIPS capable of establishing wireless communications with the remote device, such as the AIPS shown in U.S. Patent Application Publication US 2004/130915A1 to Baarman, which is entitled "Adapted Inductive Power Supply with Communication" and was published on July 8, 2004 (U.S. Serial No. 10/689,148, filed on October 20, 2003), which is incorporated herein by reference.
II. Remote Devices.

The present invention is intended for use with a wide variety of remote devices of varying designs and constructions. It is anticipated that these various remote devices will require power at varying frequency and will have different current requirements.

In some applications, the remote device may inherently include a unique resonant frequency or pattern of resonant frequencies. For example, a specific type of remote device may include a resonant frequency at 195 kHz. If none of the other remote devices to be identified by the AIPS include a resonant frequency at 195 kHz, then 195 kHz can operate as the identification frequency for this type of remote device. On the other hand, if the remote device does not include a resonant frequency that is unique among the set of remote devices that may need to be identified, then it may be possible to use the presence of a unique pattern of resonant frequencies to identify the remote device. For example, a remote device may have one resonant frequency at 195 kHz and another resonant frequency at 215 kHz. Even if other remote devices have a resonant frequency at 195 kHz or at 215 kHz, the combination of the two resonant frequencies in a single type of remote device may be sufficient to uniquely identify the type of remote device. If two resonant frequencies are not sufficient to uniquely identify a type of remote devices, then even more resonant frequencies may be considered until a unique pattern of identification frequencies emerges.

For purposes of disclosure, one embodiment of a remote device 14 having an inherent identification frequency is shown in Fig. 2. In the embodiment of Fig. 2, the remote device 14 generally includes a secondary 22 for receiving power from the AIPS 12, a bridge 30 (or other rectifier for converting AC power to DC), a charging circuit 32, a battery 34 and a main circuit 36. In operation, the bridge 30 converts the AC power generated in the secondary 22 to DC power, which is required for operation of charging circuit 32 in this embodiment. Charging circuits are well-known and are widely used with a variety of
rechargeable electronic devices. If desired, the charging circuit 32 may be configured to both charge the battery 34 and/or power the remote device 14 (if the remote device 14 is powered on). Charge circuits capable of charging and/or powering an electronic device are well-known and therefore will not be described in detail. In some applications, the charging circuit 32 will be a part of the main circuit 36. In other applications, the charging circuit 32 will be a separate circuit, and may even be controlled by the AIPS 12, if desired. The term "main circuit" is used loosely to refer to the operating circuitry for the remote device 14.

Although the illustrated embodiment is described in connection with a battery-powered remote device, the present invention may alternatively be used to directly power a remote device by eliminating the battery 34 and charging circuit 32 and connecting the secondary 22 to the main circuit 36, for example, through appropriate power conditioning circuitry, which may include a transformer or rectifier (such as bridge 30).

In another embodiment, a remote device may be provided with one or more identification capacitors that provide resonance at desired identification frequencies. Although useable with all remote devices, this embodiment is perhaps most useful with remote devices that do not have an inherent identification frequency or inherent identification pattern of frequencies. Fig. 3A shows a circuit diagram of an exemplary remote device 14’ having an identification capacitor 38’. As shown in Fig. 3A, an identification capacitor 38’ is connected in parallel across the secondary 22’. The identification capacitor 38’ has a capacitance selected to establish resonance at the identification frequency. In this embodiment, it is possible that the charging circuit 32’ and/or the main circuit 36’ will mask the identification capacitor 38’ making it difficult or impossible for the AIPS 12 to recognize the presence of the identification capacitor 38’. Accordingly, in this embodiment, the remote device 14’ includes a load enable delay circuit 54’ that prevents the charging circuit 32’ and/or the main circuit 36’ from receiving power for a period of time sufficient for the
identification capacitor 38' to establish resonance and for that resonance to be conveyed to
the AIPS 12 through reflected impedance. The load enable delay circuit 54' may include a
simple timed switching circuit that connects the bridge 30' to the charging circuit 32' only
after a sufficient period of time has lapsed. This embodiment is particularly well-suited for
incorporating the present invention into remote devices already including a charging circuit.
Fig. 4 shows an alternative embodiment intended primarily for use in incorporating the
present invention into remote devices not already including charging circuitry or that include
charging circuitry having a microprocessor with an enable input. In this embodiment, the
load enable delay 54" is connected to the "enable" input of the microprocessor in the
charging circuitry 32". In this embodiment, the load enable delay 54" does not enable the
charging circuitry 32" until a sufficient amount of time has passed for the AIPS 12 to
recognize whether or not the identification capacitor 38" has established resonance.
Although described in connection with two specific embodiment, the load enable delay
circuit may be essentially any circuitry capable of preventing the charging circuit and/or main
circuit from masking the identification capacitor long enough for the AIPS 12 to recognize
whether resonance has been established.

In the embodiment of Fig. 3A, the remote device 14' includes only a single
identification capacitor 38'. In the embodiment shown in Fig. 3B, the remote device 14" is
provided with three identification capacitors 38a-c" connected in parallel to the load each
providing resonance at a different frequency. In a similar manner, additional identification
capacitors can be provided to establish even more additional resonant frequencies, if desired.
For example, Fig. 5 is a table showing the resonance frequencies that may be provided using
different combinations of four capacitors. The first four columns labeled C1-C4 list the
capacitance (in microfarads) of four different capacitors. In this example, the capacitors are
8.2, 6.8, 3.3, and 2.2 microfarad capacitors. The capacitors used in this table or merely
exemplary and are not intended to limit the scope of the present invention. The second four columns labeled C1-C4 identify the capacitors included in that particular combination, using a "1" to represent the presence of a capacitor and a "0" to represent the absence of a capacitor. The column labeled "Capacitance" provides the combined capacitance of the capacitors in that particular combination. The column labeled "Frequency" provides the resonant frequency of the capacitor combination when the inductance is 0.000000309 as specified in the last column. For example, row four includes a "1" in the C1 and C2 columns to indicate that an 8.2 microfarad capacitor and a 6.8 microfarad capacitor are combined to provide a combined capacitance of 3.7173 microfarad, which will have a resonant frequency of roughly 148.5 kHz. In addition to the resonant frequency created by the combined capacitance of the two capacitors, the identification capacitors will also establish resonance at the individual capacitances of each capacitor in that combination. So, continuing with the row 4 example, the combined capacitors will also have a resonant frequency at roughly 100 kHz (the resonance frequency of the 8.2 microfarad capacitor) and at roughly 109.9 kHz (the resonance frequency of the 6.8 microfarad capacitor). As can be seen, the combination of 8.2 and 6.8 microfarad capacitors provides an identification frequency pattern with resonance at roughly 100 kHz, 109.9 kHz and 148.5 kHz.

The particular remote devices described above are merely exemplary as the present invention is well-suited for use with essentially any remote device having an identification frequency and capable of inductively receiving power within the limits of the AIPS.

III. Operation.

General operation of the system 10 is described in connection with Fig. 6. In this embodiment, the system 10 is configured to recognize one of a plurality of remote
devices. Each remote device includes a single resonant frequency that is unique among the remote devices. Accordingly, the AIPS 12 can uniquely identify a remote device by cycling through each of the potential identification frequencies until a remote device is present that establishes resonance at one of the potential identification frequencies.

In the illustrated embodiment, the AIPS 12 is provided with data defining a plurality of potential identification frequencies. For example, a list or table of potential identification frequencies may be stored in onboard memory on the microcontroller 40. The identification process begins by setting 100 the identification frequency to the first frequency in the list. The AIPS 12 then applies 102 power to the tank circuit 48 at the identification frequency. The AIPS 12 continues to apply power to the tank circuit 48 for a period of delay 104. The delay period is selected to provide sufficient time for the remote device 14 to establish resonance and to generate sufficient reflected impedance in the tank circuit 48. The delay period may be a fixed period of time that remains constant throughout the identification process. The delay period may vary from application to application, but in the illustrated embodiment is approximately 6 microseconds. In some applications, a sufficient delay may be inherent in the system and therefore may not require the implementation of a separate deliberate delay step. If the remote device 14 includes a resonant frequency at the identification frequency, the remote device 14 will draw current and this increase in current draw will be reflected back into the tank circuit 48 by reflected impedance. After the delay 104 is complete, the microprocessor 40 obtains 106 input from the current sensor 16. As noted above, the output of the current sensor 16 may be conditioned using conditioning circuitry 28. The microprocessor 40 evaluates the input from the current sensor 16 to determine whether the remote device 14 has a resonant frequency at the current identification frequency. In this embodiment, the microprocessor 40 will conclude that a resonant frequency exists if the current sensor reading is above a threshold value. Typically, the
threshold value for a specific application will be a value above the noise floor of that application plus an additional deadband. The amount of the deadband may vary from application to application.

If the microprocessor 40 determines that the remote device 14 does not include a resonant frequency at the current identification frequency, then the controller 20 prepares to apply to the next identification frequency to the tank circuit 48. More specifically, the microprocessor 40 enters a delay 114 for a relatively short period of time. The delay period is selected to provide sufficient time for the remote device 14 to settle and for the energy in the remote device 14 to sufficiently dissipate. The delay period may be a fixed period of time that remains constant from throughout the identification process. The settle delay period may vary from application to application, but in the illustrated embodiment is approximately 5 microseconds. In some applications, a sufficient delay may be inherent in the system and therefore may not require the implementation of a separate deliberate settle delay step. After the delay, the microprocessor 40 sets the identification frequency as the next frequency in the list of potential identification frequencies. The process then repeats beginning with the step of applying 102 power to the tank circuit 48 at the new identification frequency.

If the microprocessor 40 determines that the remote device 14 includes a resonant frequency at the current identification frequency, the microprocessor 40 will retrieve 110 the operating parameters from the lookup table 24 and will exit the remote device identification process. The microprocessor 40 may then operate 112 the remote device 14 using the operating parameters retrieved from lookup table 24. The lookup table 24 may include an anticipated operating frequency and may begin operation by applying power to the tank circuit 48 at the recalled operating frequency. The microprocessor 40 may also use maximum and minimum current draws values obtained from the lookup table to determine the presence of a fault condition. For example, if during operation the actual current draw
sensed by the current sensor exceeds the maximum current draw or falls below the minimum current draw, the microprocessor 40 will conclude that a fault condition exists. The microprocessor 40 may be programmed to take remedial action if a fault condition is encountered. For example, the microprocessor 40 may be programmed to shut down the system if a fault condition arises. Alternatively, the microprocessor 40 may restart the identification process to determine if a different remote device 40 has been placed near the primary 18.

In the embodiment described above, the microprocessor 40 cycles through a list of potential identification frequencies in an effort to identify a remote device. As an alternative to cycling through a list, the AIPS 12 may be programmed to simply cycle through a range of frequencies using a specified step value. For example, by stepping from 100 kHz to 300kHz in 5 kHz increments.

In another aspect, the present invention provides a mechanism for establishing standards for using frequency identification for remote devices. In this embodiment, unique identification frequencies can be specified for each type of remote device and for other identifying features. For example, the standards may specify a different identification frequency for each type of device (e.g. cell phone, personal digital assistant, may digital music player) and/or for each manufacturer (e.g. company name). In applications where a unique identification frequency is assigned to each manufacturer, the manufacturer may be permitted to add additional identification frequencies to specify model numbers and product types.

In an alternative method for establishing standards, identification frequencies can be establish by the class of the remote device rather than the specific model type. For example, all devices operating within a given set of operating parameters can be assigned the same identification frequency (or identification frequency pattern). This alternative method
is particularly well-suited for use in application where a plurality of remote devices of
different types are capable of operating under the operating parameters set forth in a single
record in the lookup table.

According to another embodiment, each device capable of being inductively
powered or charged by an inductive power supply is provided with at least one common
resonant frequency, and at least one unique frequency. For example, referring to the above
embodiments and the figures, each device capable of being charged by AIPS 12 is provided
with an 8.2 microfarad capacitor, providing the device with a primary identification resonant
frequency of 100kHz. AIPS 12 repeatedly sends out a pulse at approximately 100kHz. If a
device 14 with a resonant frequency of 100kHz is placed within the field generated by AIPS
12, then AIPS proceeds with a sweep of additional frequencies to identify the type of device
14. According to one embodiment, the charging circuit of each individual battery type is
provided with a second unique resonant frequency, or secondary identification frequency.
For example, each lithium ion battery is further comprised of a capacitor or other circuitry to
provide a secondary resonant frequency at 109.4 kHz; each nickel cadmium battery is
provided with a capacitor or other circuitry to provide a secondary resonant frequency at
148.5 kHz. According to another embodiment, each battery may further equipped with a
capacitor or other circuitry to provide a tertiary resonant frequency used to identify the
individual manufacturer or supplier of that battery. For example, each inductively charged
lithium ion battery manufactured or sold by vendor X is provided with one or more capacitors
or other circuitry to provide a primary identification resonant frequency of 100kHz, a
secondary identification resonant frequency of 109.4 kHz, and a tertiary identification
resonant frequency of 130kHz. Each lithium ion battery manufactured or sold by vendor Y is
provided with one or more capacitors or other circuitry to provide a primary identification
resonant frequency of 100kHz, a secondary identification resonant frequency of 109.4 kHz,
and a tertiary identification resonant frequency of 140kHz. According to another embodiment, an additional identification resonant frequency may be added to distinguish, for example, different types of inductively charged lithium ion batteries sold by vendor X or vendor Y. Such identification could allow AIPS to adjust the charging or power control not only according to the requirements of various load types as discussed above, but according to specific requirements of individual manufacturers or suppliers of those load types. It would be obvious that such identification strategies and protocols could be used to identify inductive loads that are not only powered by a rechargeable battery, but also to identify those loads that are directly inductively powered.

The standards discussed above rely on the assignment of a range of identification frequencies. The spacing between identification frequencies may vary from application to application depending of the resolution of the AIPS sensing the present of resonance during the identification process. For example, an AIPS with sufficient resolution to accurately recognize frequency differences of 5 kHz can use a separation of 5 kHz between identification frequencies (e.g. 250 kHz and 255 kHz). An AIPS with lower resolution may require greater separation between identification frequencies (e.g. 250 kHz and 260kHz).

The above description is that of current embodiments of the invention. Various alterations and changes can be made without departing from the spirit and broader aspects of the invention as defined in the appended claims, which are to be interpreted in accordance with the principles of patent law including the doctrine of equivalents. Any reference to claim elements in the singular, for example, using the articles "a," "an," "the" or "said," is not to be construed as limiting the element to the singular.
CLAIMS

The embodiments of the invention in which an exclusive property or privilege is claimed are defined as follows:

1. A method for controlling an inductive power supply, comprising the steps of:
   associating an identification frequency with a remote device, the identification frequency including at least one frequency at which the remote device has a resonant frequency;
   applying an inductive field to a remote device at the identification frequency;
   determining whether the remote device has a resonant frequency substantially at the applied identification frequency; and
   operating the inductive power supply based on an outcome of said determining step.

2. The method of claim 1 wherein said operating step is further defined as the steps of:
   retrieving at least one parameter for the remote device from a memory associated with the inductive power supply, if the remote device has a resonant frequency substantially at the applied identification frequency; and
   after said retrieving step, operating the inductive power supply to apply power to the remote device in accordance with the parameter.

3. The method of claim 2 further including the step of storing in memory at least one parameter for the remote device associated with the identification frequency.

4. The method of claim 3 wherein said associating step is further defined as associating a plurality of different identification frequencies with a plurality of different remote devices; and
wherein said applying step and said determining step are repeated for each of the different identification frequencies until the remote device is determined to have a resonant frequency substantially at the applied identification frequency.

5. The method of claim 4 wherein said storing step is further defined as storing in memory at least one parameter for each of the plurality of different remote devices.

6. The method of claim 5 further including the step of actively configuring each of the plurality of remote devices to include a resonant frequency at a desired unique frequency, the identification frequency including the resonant frequency, whereby each of said plurality of remote devices may be uniquely identified by its corresponding identification frequency.

7. The method of claim 5 further including the step of actively configuring each of the plurality of remote devices to include a plurality of resonant frequencies, the identification frequency associated with each of the remote devices including the plurality of resonant frequencies included in that remote device, whereby each remote device may be uniquely identified by the plurality of resonant frequencies.

8. The method of claim 6 wherein said step of actively configuring each of the plurality of remote devices includes the step of incorporating a capacitor into each of the plurality of remote devices to provide a resonant frequency corresponding to the capacitor value.

9. A method for operating an inductive power supply comprising the steps of:

   - storing a plurality of identification profiles and at least one operating parameter associated with each identification profile in a memory associated with an inductive power supply;
   - applying inductive power to a remote device at one or more frequencies to determine the identification profile of the remote device contained within the inductive field;
   - comparing the determined profile with the stored identification profiles to determine an identity of the remote device;
retrieving an operating parameter from the memory upon determination of the identity of the remote device; and

operating the inductive power supply in accordance with the retrieved operating parameter.

10. The method of claim 9 further including the step of determining an inherent resonant frequency profile of a remote device to determine the identification profile for the remote device.

11. The method of claim 9 further including the step of providing a remote device with an identification profile.

12. The method of claim 11 wherein said step of providing a remote device with an identification profile includes the step of incorporating an identification capacitor into the remote device.

13. The method of claim 11 wherein said step of providing a remote device with an identification profile includes the step of incorporating a plurality of identification capacitors into the remote device.

14. The method of claim 9 wherein each of the identification profiles includes one or more resonant frequencies.

15. The method of claim 14 wherein said applying step includes the steps of:

applying a pulse of power at the one or more frequencies associated with the stored profile; and

sensing current in the tank circuit to determine whether the remote device has a resonant frequency at the one or more applied frequencies.

16. A method for securely controlling an inductive power supply, comprising the steps of:
determining a common identification profile for remote devices to be powered by the inductive power supply, the common identification profile including one or more resonant frequencies;

providing each remote device to be powered by the inductive power supply with the common identification profile;

applying an inductive field to a remote device at the one or more resonant frequencies of the common identification profile;

determining whether said remote device has a resonant frequency profile corresponding with the common identification profile; and

operating the inductive power supply to power the remote device if the remote device has a resonant frequency profile corresponding with the common identification profile.

17. The method of claim 16 further including the steps of:

providing each remote device to be powered by the inductive power supply with a unique identification profile;

storing the plurality of unique identification profiles and an associated operating parameter in a memory associated with the inductive power supply;

once it is determined that the remote device has a resonant frequency profile corresponding with the common identification profile, applying an inductive field to the remote device at one or more resonant frequencies corresponding to one or more of the unique identification profiles;

determining whether said remote device has a resonant frequency profile corresponding with one of the unique identification profiles;

retrieving the associated operating parameter from the memory upon determining that the remote device corresponds with one of the unique identification profiles; and
following said retrieving step, operating the inductive power supply in accordance
with the retrieved operating parameter to power the remote device.

18. An inductive power supply comprising:

inductive field generating circuitry;

frequency control circuitry electrically connected to said inductive field generating

circuitry, said control circuitry capable of operating said inductive field generating circuitry

at a plurality of different frequencies;

reflected impedance sensing circuitry to sense a characteristic of power in the

inductive power supply, said characteristic being indicative of a reflected impedance of a

remote device;

identification circuitry to determine an identification profile of a remote device as a

function of output of said reflected impedance sensing circuitry; and

power supply control circuitry for supplying power to the remote device as a function

of the identification profile of the remote device.

19. The inductive power supply of claim 18 wherein said inductive field generating

circuitry includes a tank circuit having a primary.

20. The inductive power supply of claim 19 wherein said frequency control circuitry

includes an oscillator and a driver.

21. The inductive power supply of claim 20 wherein said reflected impedance sensing

circuitry includes a current sense transformer coupled to said tank circuit.

22. The inductive power supply of claim 21 wherein said identification circuitry includes

a microcontroller and a memory, said memory storing a plurality of identification profiles for
different remote devices and a plurality of operating parameters, each of said operating
parameters associated with one or more of the plurality of identification profiles.

23. An inductive power supply and remote device combination comprising:
a remote device having an identification profile, said identification profile including one or more resonant frequencies; and

an inductive power supply having:

a driver;

a tank circuit having a primary;

a sensor in said tank circuit adapted to sense a characteristic of power in said tank circuit indicative of a reflected impedance of said remote device;

identification circuitry to determine said identification profile of said remote device as a function of output of said sensor; and

control circuitry for controlling operation of said inductive power supply as a function of said identification profile of said remote device.

24. The combination of claim 23 wherein said inductive power supply includes a memory storing at least one identification profile and at least one operating parameter associated with said identification profile.

25. The combination of claim 23 wherein said remote device includes an identification capacitor.

26. The combination of claim 23 wherein said identification profile includes an inherent resonant frequency of said remote device.

## INTERNATIONAL SEARCH REPORT

**International application No**

PCT/IB2007/055339

### A. CLASSIFICATION OF SUBJECT MATTER

INV. G06K7/00 G06K19/07 H04B5/00 H02J7/02

According to International Patent Classification (IPC) or to both national classification and IPC

### B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

G06K H04B H02J

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, WPI Data

### C. DOCUMENTS CONSIDERED TO BE RELEVANT

[See patent family annex](#)

[X] Further documents are listed in the continuation of Box C

[X] Special categories of cited documents

A. document defining the general state of the art which is not considered to be of particular relevance

E. earlier document but published on or after the international filing date

L. document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

O. document relating to an oral disclosure, use exhibition or other means

P. document published prior to the international filing date but later than the priority date claimed

T. later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

X. document of particular relevance, the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

Y. document of particular relevance, the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

A. document member of the same patent family
