FIELD OF THE INVENTION

The present invention relates to 2,3-Substituted Indole Derivatives, compositions comprising at least one 2,3-Substituted Indole Derivative, and methods of using the 2,3-Substituted Indole Derivatives for treating or preventing a viral infection or a virus-related disorder in a patient.

BACKGROUND OF THE INVENTION

HCV is a (+)-sense single-stranded RNA virus that has been implicated as the major causative agent in non-A, non-B hepatitis (NANBH). NANBH is distinguished from other types of viral-induced liver disease, such as hepatitis A virus (HAV), hepatitis B virus (HBV), hepatitis delta virus (HDV), as well as from other forms of liver disease such as alcoholism and primary biliary cirrhosis.

Hepatitis C virus is a member of the hepacivirus genus in the family Flaviviridae. It is the major causative agent of non-A, non-B viral hepatitis and is the major cause of transfusion-associated hepatitis and accounts for a significant proportion of hepatitis cases worldwide. Although acute HCV infection is often asymptomatic, nearly 80% of cases resolve to chronic hepatitis. About 60% of patients develop liver disease with various clinical outcomes ranging from an asymptomatic carrier state to chronic active hepatitis and liver cirrhosis (occurring in about 20% of patients), which is strongly associated with the development of hepatocellular carcinoma (occurring in about 1-5% of patients). The World Health Organization estimates that 170 million people are chronically infected with HCV, with an estimated 4 million living in the United States.

HCV has been implicated in cirrhosis of the liver and in induction of hepatocellular carcinoma. The prognosis for patients suffering from HCV infection remains poor as HCV infection is more difficult to treat than other forms of hepatitis. Current data indicates a four-year survival rate of below 50% for patients suffering from cirrhosis and a five-year survival rate of below 30% for patients diagnosed with localized resectable hepatocellular carcinoma. Patients diagnosed with localized unresectable hepatocellular carcinoma fare even worse, having a five-year survival rate of less than 1%.
HCV is an enveloped RNA virus containing a single-stranded positive-sense RNA genome approximately 9.5 kb in length. The RNA genome contains a 5'-nontranslated region (5' NTR) of 341 nucleotides, a large open reading frame (ORF) encoding a single polypeptide of 3,010 to 3,040 amino acids, and a 3'-nontranslated region (3'-NTR) of variable length of about 230 nucleotides. HCV is similar in amino acid sequence and genome organization to flaviviruses and pestiviruses, and therefore HCV has been classified as a third genus of the family Flaviviridae.

The 5' NTR, one of the most conserved regions of the viral genome, contains an internal ribosome entry site (IRES) which plays a pivotal role in the initiation of translation of the viral polyprotein. A single long open reading frame encodes a polyprotein, which is co- or post-translationally processed into structural (core, E1, E2 and p7) and nonstructural (NS2, NS3, NS4A, NS4B, NS5A, and NS5B) viral proteins by either cellular or viral proteinases. The 3' NTR consists of three distinct regions: a variable region of about 38 nucleotides following the stop codon of the polyprotein, a polyuridine tract of variable length with interspersed substitutions of cytidines, and 98 nucleotides (nt) at the very 3' end which are highly conserved among various HCV isolates. By analogy to other plus-strand RNA viruses, the 3'-NTR is thought to play an important role in viral RNA synthesis. The order of the genes within the genome is: NH$_2$-C-E1-E2-p7-NS2-NS3-NS4A-NS4B-NS5A-NS5B-COOH.

Processing of the structural proteins core (C), envelope protein 1 and (E1, E2), and the p7 region is mediated by host signal peptidases. In contrast, maturation of the nonstructural (NS) region is accomplished by two viral enzymes. The HCV polyprotein is first cleaved by a host signal peptidase generating the structural proteins C/El, E1/E2, E2/p7, and p7/NS2. The NS2-3 proteinase, which is a metalloprotease, then cleaves at the NS2/NS3 junction. The NS3/4A proteinase complex (NS3 being a serine protease and NS4A acting as a cofactor of the NS3 protease), is then responsible for processing all the remaining cleavage junctions. RNA helicase and NTPase activities have also been identified in the NS3 protein. One-third of the NS3 protein functions as a protease, and the remaining two-thirds of the molecule acts as the helicase/ATPase that is thought to be involved in HCV replication. NS5A may be phosphorylated and acts as a putative cofactor of NS5B. The fourth viral enzyme, NS5B, is a membrane-associated RNA-dependent RNA polymerase (RdRp) and a key component responsible for replication of the viral RNA genome. NS5B contains the "GDD" sequence motif, which is highly conserved among all RdRps characterized to date.
Replication of HCV is thought to occur in membrane-associated replication complexes. Within these, the genomic plus-strand RNA is transcribed into minus-strand RNA, which in turn can be used as a template for synthesis of progeny genomic plus-strands. At least two viral enzymes appear to be involved in this reaction: the NS3 helicase/NTPase, and the NS5B RNA-dependent RNA polymerase. While the role of NS3 in RNA replication is less clear, NS5B is the key enzyme responsible for synthesis of progeny RNA strands. Using recombinant baculoviruses to express NS5B in insect cells and a synthetic nonviral RNA as a substrate, two enzymatic activities have been identified as being associated with it: a primer-dependent RdRp and a terminal transferase (TNTase) activity. It was subsequently confirmed and further characterized through the use of the HCV RNA genome as a substrate. Other studies have shown that NS5B with a C-terminal 21 amino-acid truncation expressed in Escherichia coli is also active for in vitro RNA synthesis. On certain RNA templates, NS5B has been shown to catalyze RNA synthesis via a de novo initiation mechanism, which has been postulated to be the mode of viral replication in vivo. Templates with single-stranded 3' termini, especially those containing a 3'-terminal cytidylate moiety, have been found to direct de novo synthesis efficiently. There has also been evidence for NS5B to utilize di- or tri-nucleotides as short primers to initiate replication.

It is well-established that persistent infection of HCV is related to chronic hepatitis, and as such, inhibition of HCV replication is a viable strategy for the prevention of hepatocellular carcinoma. Present treatment approaches for HCV infection suffer from poor efficacy and unfavorable side-effects and there is currently a strong effort directed to the discovery of HCV replication inhibitors that are useful for the treatment and prevention of HCV related disorders. New approaches currently under investigation include the development of prophylactic and therapeutic vaccines, the identification of interferons with improved pharmacokinetic characteristics, and the discovery of agents designed to inhibit the function of three major viral proteins: protease, helicase and polymerase. In addition, the HCV RNA genome itself, particularly the IRES element, is being actively exploited as an antiviral target using antisense molecules and catalytic ribozymes.

Particular therapies for HCV infection include α-interferon monotherapy and combination therapy comprising α-interferon and ribavirin. These therapies have been shown to be effective in some patients with chronic HCV infection. The use of antisense oligonucleotides for treatment of HCV infection has also been proposed as has the use of free
bile acids, such as ursodeoxycholic acid and chenodeoxycholic acid, and conjugated bile acids, such as tauroursodeoxycholic acid. Phosphonoformic acid esters have also been proposed as potentially for the treatment of various viral infections including HCV. Vaccine development, however, has been hampered by the high degree of viral strain heterogeneity and immune evasion and the lack of protection against reinfection, even with the same inoculum.

The development of small-molecule inhibitors directed against specific viral targets has become a major focus of anti-HCV research. The determination of crystal structures for NS3 protease, NS3 RNA helicase, and NS5B polymerase has provided important structural insights that should assist in the rational design of specific inhibitors.

NS5B, the RNA-dependent RNA polymerase, is an important and attractive target for small-molecule inhibitors. Studies with pestiviruses have shown that the small molecule compound VP32947 (3-[((2-dipropylamino)ethyl)thio]-5H-1,2,4-triazino[5,6-b]indole) is a potent inhibitor of pestivirus replication and most likely inhibits the NS5B enzyme since resistant strains are mutated in this gene. Inhibition of RdRp activity by (-)β-L-2',3'-dideoxy-3'-thiacytidine 5'-triphosphate (3TC; lamivudine triphosphate) and phosphonoacetic acid also has been observed.

Despite the intensive effort directed at the treatment and prevention of HCV and related viral infections, there exists a need in the art for non-peptide, small-molecule compounds having desirable or improved physicochemical properties that are useful for inhibiting viruses and treating viral infections and virus-related disorders.

The term "substituted," as used herein, means that one or more hydrogens on the designated atom is replaced with a selection from the indicated group, provided that the designated atom's normal valency under the existing circumstances is not exceeded, and that the substitution results in a stable compound. Combinations of substituents and/or variables are permissible only if such combinations result in stable compounds. By "stable compound" or "stable structure" is meant a compound that is sufficiently robust to survive isolation to a useful degree of purity from a reaction mixture, and formulation into an efficacious therapeutic agent.

The term "optionally substituted" as used herein, means optional substitution with the specified groups, radicals or moieties.

The terms "purified", "in purified form" or "in isolated and purified form" as used herein, for a compound refers to the physical state of said compound after being isolated from
a synthetic process (e.g. from a reaction mixture), or natural source or combination thereof. Thus, the term "purified", "in purified form" or "in isolated and purified form" for a compound refers to the physical state of said compound after being obtained from a purification process or processes described herein or well known to the skilled artisan (e.g., chromatography, recrystallization and the like), in sufficient purity to be characterizable by standard analytical techniques described herein or well known to the skilled artisan.

It should also be noted that any carbon as well as heteroatom with unsatisfied valences in the text, schemes, examples and Tables herein is assumed to have the sufficient number of hydrogen atom(s) to satisfy the valences.

When a functional group in a compound is termed "protected", this means that the group is in modified form to preclude undesired side reactions at the protected site when the compound is subjected to a reaction. Suitable protecting groups will be recognized by those with ordinary skill in the art as well as by reference to standard textbooks such as, for example, T. W. Greene et al, Protective Groups in organic Synthesis (1991), Wiley, New York.

When any variable (e.g., aryl, heterocycle, R₁¹, etc.) occurs more than one time in any constituent or in Formula (I) or (H), its definition on each occurrence is independent of its definition at every other occurrence, unless otherwise noted.

Prodrugs and solvates of the compounds of the invention are also contemplated herein. A discussion of prodrugs is provided in T. Higuchi and V. Stella, Pro-drugs as Novel Delivery Systems (1987) 14 of the A.C.S. Symposium Series, and in Bioreversible Carriers in Drug Design, (1987) Edward B. Roche, ed., American Pharmaceutical Association and Pergamon Press. The term "prodrug" as used herein, refers to a compound (e.g., a drug precursor) that is transformed in vivo to provide a 2,3-Substituted Indole Derivative or a pharmaceutically acceptable salt, hydrate or solvate of the compound. The transformation may occur by various mechanisms (e.g., by metabolic or chemical processes), such as, for example, through hydrolysis in blood. A discussion of the use of prodrugs is provided by T. Higuchi and W. Stella, "Pro-drugs as Novel Delivery Systems," Vol. 14 of the A.C.S. Symposium Series, and in Bioreversible Carriers in Drug Design, ed. Edward B. For example, if a 2,3-Substituted Indole Derivative or a pharmaceutically acceptable salt, hydrate or solvate of the compound contains a carboxylic acid functional group, a prodrug can comprise an ester formed by the replacement of the hydrogen atom of the acid group with
a group such as, for example, \((\text{Ci-C}_8)\)alkyl, \((\text{C}_2-\text{C}_{12})\)alkanoyloxymethyl, 1-(alkanoyloxy)ethyl having from 4 to 9 carbon atoms, 1-methyl-1-(alkanoyloxy)-ethyl having from 5 to 10 carbon atoms, alkoxy carbonyloxymethyl having from 3 to 6 carbon atoms, 1-(alkoxy carbonyloxy)ethyl having from 4 to 7 carbon atoms, 1-methyl-1-(alkoxy carbonyloxy)ethyl having from 5 to 8 carbon atoms, N-(alkoxycarbonyl)aminomethyl having from 3 to 9 carbon atoms, 1-(N-(alkoxycarbonyl)amino)ethyl having from 4 to 10 carbon atoms, 3-phthalidyl, 4-crotonolactonyl, gamma-butyrolacton-4-yl, di-N,N-(\text{C}_1-\text{C}_2)alkylamino(\text{C}_2-\text{C}_3)alkyl (such as \(\beta\)-dimethylaminoethyl), carbamoyl-(\text{Ci-C}_2)alkyl, N,N-di(\text{C}_1\text{-C}_2)alkylcarbamoyl-(\text{Ci-C}_2)alkyl and piperidino-, pyrrolidino- or \(\text{m}\phi\) holino(\text{C}_2-\text{C}_3)alkyl, and the like.

Similarly, if a 2,3-Substituted Indole Derivative contains an alcohol functional group, a prodrug can be formed by the replacement of the hydrogen atom of the alcohol group with a group such as, for example, \((\text{C}_1-\text{C}_6)\)alkanoyloxymethyl, 1-((\text{C}_1-\text{C}_6)alkanoyloxy)ethyl, 1-methyl-1-((\text{C}_1-\text{C}_6)alkanoyloxy)ethyl, \((\text{Ci-C}_6)\)alkoxycarbonyloxymethyl, \((\text{m}\phi\) holino(\text{C}_2-\text{C}_6)alkyl) and aminomethyl, succinoyl, \((\text{Ci-C}_6)\)alkanoyl, \(\alpha\)-amino(\text{Ci-C}_2)alkanyl, arylacetyl and \(\alpha\)-aminoacetyl, or \(\alpha\)-aminoacetyl-\(\alpha\)-aminoacetyl, where each \(\alpha\)-aminoacetyl group is independently selected from the naturally occurring \(L\)-amino acids, \(\text{P(O)(O(Ci-C}_6)alkyl)\), or glycosyl (the radical resulting from the removal of a hydroxyl group of the hemiacetal form of a carbohydrate), and the like.

If a 2,3-Substituted Indole Derivative incorporates an amine functional group, a prodrug can be formed by the replacement of a hydrogen atom in the amine group with a group such as, for example, \(R\)-carbonyl, \(R'\)-carbonyl, \(\text{NRR}'\)-carbonyl where \(R\) and \(R'\) are each independently \((\text{Ci-C}_6)\)alkyl, \((\text{C}_5-\text{C}_7)\) cycloalkyl, benzyl, or \(R\)-carbonyl is a natural \(\alpha\)-aminoacetyl or natural \(\alpha\)-aminoacetyl, \(\text{C(OH)C(O)OY}^1\) wherein \(Y^1\) is \(\text{H, (Ci-C}_6)\)alkyl or benzyl, \(\text{C(OY}^2)\)Y\(^3\) wherein \(Y^2\) is \((\text{Ci-C}_4)\) alkyl and \(Y^3\) is \((\text{Ci-QOalkyl, carboxy (d-C}_6\) alkyl, amino(\text{Ci-C}_4)\)alkyl or mono-N— or di-N,N-(\text{Ci-C}_6)alkylaminoalkyl, \(\text{C(Y}^4)\)Y\(^5\) wherein \(Y^4\) is \(\text{H or methyl and Y}^5\) is mono-N— or di-N,N-(\text{Ci-C}_6)alkylamino morpholino, piperidin-1-yl or pyrrolidin-1-yl, and the like.

One or more compounds of the invention may exist in unsolvated as well as solvated forms with pharmaceutically acceptable solvents such as water, ethanol, and the like, and it is intended that the invention embrace both solvated and unsolvated forms. "Solvate" means a physical association of a compound of this invention with one or more solvent molecules. This
physical association involves varying degrees of ionic and covalent bonding, including hydrogen bonding. In certain instances the solvate will be capable of isolation, for example when one or more solvent molecules are incorporated in the crystal lattice of the crystalline solid. "Solvate" encompasses both solution-phase and isolatable solvates. Non-limiting examples of illustrative solvates include ethanolates, methanolates, and the like. "Hydrate" is a solvate wherein the solvent molecule is H₂O.

One or more compounds of the invention may optionally be converted to a solvate. Preparation of solvates is generally known. Thus, for example, M. Caira et al, J. Pharmaceutical Sd., 93(3), 601-611 (2004) describe the preparation of the solvates of the antifungal fluconazole in ethyl acetate as well as from water. Similar preparations of solvates, hemisolvate, hydrates and the like are described by E. C. van Tonder et al, AAPS PharmSciTech., 5(JQ), article 12 (2004); and A. L. Bingham et al, Chem. Commun., 603-604 (2001). A typical, non-limiting, process involves dissolving the inventive compound in desired amounts of the desired solvent (organic or water or mixtures thereof) at a higher than ambient temperature, and cooling the solution at a rate sufficient to form crystals which are then isolated by standard methods. Analytical techniques such as, for example I.R. spectroscopy, show the presence of the solvent (or water) in the crystals as a solvate (or hydrate).

The term "effective amount" or "therapeutically effective amount" is meant to describe an amount of compound or a composition of the present invention that is effective to treat or prevent a viral infection or a virus-related disorder.

Metabolic conjugates, such as glucuronides and sulfates which can undergo reversible conversion to the 2,3-Substituted Indole Derivatives are contemplated in the present invention.

The 2,3-Substituted Indole Derivatives may form salts, and all such salts are contemplated within the scope of this invention. Reference to a 2,3-Substituted Indole Derivative herein is understood to include reference to salts thereof, unless otherwise indicated. The term "salt(s)", as employed herein, denotes acidic salts formed with inorganic and/or organic acids, as well as basic salts formed with inorganic and/or organic bases. In addition, when a 2,3-Substituted Indole Derivative contains both a basic moiety, such as, but not limited to a pyridine or imidazole, and an acidic moiety, such as, but not limited to a carboxylic acid, zwitterions ("inner salts") may be formed and are included within the term "salt(s)" as used herein. Pharmaceutically acceptable (i.e., non-toxic, physiologically acceptable) salts are preferred, although other salts are also useful. Salts of the compounds of the Formula I may be
formed, for example, by reacting a 2,3-Substituted Indole Derivative with an amount of acid or base, such as an equivalent amount, in a medium such as one in which the salt precipitates or in an aqueous medium followed by lyophilization.

Exemplary acid addition salts include acetates, ascorbates, benzoates, benzenesulfonates, bisulfates, borates, butyrates, citrates, camphorates, camphorsulfonates, fumarates, hydrochlorides, hydrobromides, hydroiodides, lactates, maleates, methanesulfonates, naphthalenesulfonates, nitrates, oxalates, phosphates, propionates, salicylates, succinates, sulfates, tartarates, thiocyanates, toluenesulfonates (also known as tosylates,) and the like. Additionally, acids which are generally considered suitable for the formation of pharmaceutically useful salts from basic pharmaceutical compounds are discussed, for example, by P. Stahl et al, Camille G. (eds.) Handbook of Pharmaceutical Salts. Properties, Selection and Use. (2002) Zurich: Wiley-VCH; S. Berge et al, Journal of Pharmaceutical Sciences (1977) 66(1) 1-19; P. Gould, InternationalJ. of Pharmaceutics (1986) 33 201-217; Anderson et al, The Practice of Medicinal Chemistry (1996), Academic Press, New York; and in The Orange Book (Food & Drug Administration, Washington, D.C. on their website). These disclosures are incorporated herein by reference thereto.

Exemplary basic salts include ammonium salts, alkali metal salts such as sodium, lithium, and potassium salts, alkaline earth metal salts such as calcium and magnesium salts, salts with organic bases (for example, organic amines) such as dicyclohexylamines, t-butyl amines, choline, and salts with amino acids such as arginine, lysine and the like. Basic nitrogen-containing groups may be quarternized with agents such as lower alkyl halides (e.g. methyl, ethyl, and butyl chlorides, bromides and iodides), dialkyl sulfates (e.g. dimethyl, diethyl, and dibutyl sulfates), long chain halides (e.g. decyl, lauryl, and stearyl chlorides, bromides and iodides), aralkyl halides (e.g. benzyl and phenethyl bromides), and others.

All such acid salts and base salts are intended to be pharmaceutically acceptable salts within the scope of the invention and all acid and base salts are considered equivalent to the free forms of the corresponding compounds for purposes of the invention.

Pharmaceutically acceptable esters of the present compounds include the following groups: (1) carboxylic acid esters obtained by esterification of the hydroxy groups, in which the non-carbonyl moiety of the carboxylic acid portion of the ester grouping is selected from straight or branched chain alkyl (for example, acetyl, n-propyl, t-butyl, or n-butyl), alkoxyalkyl (for example, methoxymethyl), aralkyl (for example, benzyl), aryloxyalkyl (for example,
phenoxymethyl), aryl (for example, phenyl optionally substituted with, for example, halogen, C^alkyl, or C^alkoxy or amino); (2) sulfonate esters, such as alkyl- or aralkylsulfonyl (for example, methanesulfonyl); (3) amino acid esters (for example, L-valyl or L-isoleucyl); (4) phosphonate esters and (5) mono-, di- or triphosphate esters. The phosphate esters may be further esterified by, for example, a C_{120} alcohol or reactive derivative thereof, or by a 2,3-di (C_{6-24})acyl glycerol.

The 2,3-Substituted Indole Derivatives may contain asymmetric or chiral centers, and, therefore, exist in different stereoisomeric forms. It is intended that all stereoisomeric forms of the 2,3-Substituted Indole Derivatives as well as mixtures thereof, including racemic mixtures, form part of the present invention. In addition, the present invention embraces all geometric and positional isomers. For example, if a 2,3-Substituted Indole Derivative incorporates a double bond or a fused ring, both the cis- and trans-forms, as well as mixtures, are embraced within the scope of the invention.

Diastereomeric mixtures can be separated into their individual diastereomers on the basis of their physical chemical differences by methods well known to those skilled in the art, such as, for example, by chromatography and/or fractional crystallization. Enantiomers can be separated by converting the enantiomeric mixture into a diastereomeric mixture by reaction with an appropriate optically active compound (e.g., chiral auxiliary such as a chiral alcohol or Mosher's acid chloride), separating the diastereomers and converting (e.g., hydrolyzing) the individual diastereomers to the corresponding pure enantiomers. Also, some of the 2,3-Substituted Indole Derivatives may be atropisomers (e.g., substituted biaryls) and are considered as part of this invention. Enantiomers can also be separated by use of chiral HPLC column.

The straight line — as a bond generally indicates a mixture of, or either of, the possible isomers, non-limiting example(s) include, containing (R)- and (S)- stereochemistry. For example,

A dashed line (-----) represents an optional bond.

Lines drawn into the ring systems, such as, for example:
indicate that the indicated line (bond) may be attached to any of the substitutable ring atoms, non limiting examples include carbon, nitrogen and sulfur ring atoms.

As well known in the art, a bond drawn from a particular atom wherein no moiety is depicted at the terminal end of the bond indicates a methyl group bound through that bond to the atom, unless stated otherwise. For example:

All stereoisomers (for example, geometric isomers, optical isomers and the like) of the present compounds (including those of the salts, solvates, hydrates, esters and prodrugs of the compounds as well as the salts, solvates and esters of the prodrugs), such as those which may exist due to asymmetric carbons on various substituents, including enantiomeric forms (which may exist even in the absence of asymmetric carbons), rotameric forms, atropisomers, and diastereomeric forms, are contemplated within the scope of this invention, as are positional isomers (such as, for example, 4-pyridyl and 3-pyridyl). For example, if a 2,3-Substituted Indole Derivative incorporates a double bond or a fused ring, both the cis- and trans-forms, as well as mixtures, are embraced within the scope of the invention.

Individual stereoisomers of the compounds of the invention may, for example, be substantially free of other isomers, or may be admixed, for example, as racemates or with all other, or other selected, stereoisomers. The chiral centers of the present invention can have the S or R configuration as defined by the IUPAC 1974 Recommendations. The use of the terms "salt", "solvate", "ester", "prodrug" and the like, is intended to equally apply to the salt, solvate, ester and prodrug of enantiomers, stereoisomers, rotamers, positional isomers, racemates or prodrugs of the inventive compounds.

The present invention also embraces isotopically-labelled compounds of the present invention which are identical to those recited herein, but for the fact that one or more atoms are replaced by an atom having an atomic mass or mass number different from the atomic mass or mass number usually found in nature. Such compounds are useful as therapeutic, diagnostic or research reagents. Examples of isotopes that can be incorporated into compounds of the
invention include isotopes of hydrogen, carbon, nitrogen, oxygen, phosphorus, fluorine and chlorine, such as $^2$H, $^3$H, $^{13}$C, $^{14}$C, $^{15}$N, $^{18}$O, $^{17}$O, $^{31}$P, $^{32}$P, $^{35}$S, $^{18}$F, and $^{36}$Cl, respectively.

Certain isotopically-labelled 2,3-Substituted Indole Derivatives (e.g., those labeled with $^3$H and $^{14}$C) are useful in compound and/or substrate tissue distribution assays. Tritiated (i.e., $^3$H) and carbon-14 (i.e., $^{14}$C) isotopes are particularly preferred for their ease of preparation and detectability. Further, substitution with heavier isotopes such as deuterium (i.e., $^2$H) may afford certain therapeutic advantages resulting from greater metabolic stability (e.g., increased in vivo half-life or reduced dosage requirements) and hence may be preferred in some circumstances. Isotopically labelled 2,3-Substituted Indole Derivatives can generally be prepared by following procedures analogous to those disclosed in the Schemes and/or in the Examples herein below, by substituting an appropriate isotopically labelled reagent for a non-isotopically labelled reagent.

Polymorphic forms of the 2,3-Substituted Indole Derivatives, and of the salts, solvates, hydrates, esters and prodrugs of the 2,3-Substituted Indole Derivatives, are intended to be included in the present invention.

5 **Methods For Making the 2,3-Substituted Indole Derivatives**

Methods useful for making the 2,3-Substituted Indole Derivatives are set forth in the Examples below and generalized in Schemes 1-6. Examples of commonly known methodologies useful for the synthesis of indoles are set forth, for example, in G. R. Humphrey and J. T. Kuethe, *Chemical Reviews* 106:2875-2911, 2006.
Scheme 1 shows a method useful for making compounds of formula iv, which are useful intermediates for making the 2,3-Substituted Indole Derivatives.

Scheme 1

wherein R^4-R^7 are defined above for the compounds of formula (I) and R is H, alkyl or aryl.

An aniline compound of formula i can be converted to an indole compound of formula iv using various indole syntheses that are well-known to those skilled in the art of organic synthesis, including but not limited to, a Fischer indole synthesis through intermediates of type ü and iü, the method set forth in Nazare et al, Angew. Chem., 116:4626-4629 (2004). The compounds of formula iv can be further elaborated to provide the 2,3-Substituted Indole Derivatives using the method described below in Scheme 4.

Scheme 2 shows methods useful for making compounds of formulas viii and x, which are useful intermediates for making of the 2,3-Substituted Indole Derivatives.
wherein $R^4$-$R^7$ are defined above for the compounds of formula (I) and $R$ is H, alkyl or aryl.

A benzene derivative of formula $v$, wherein $R^7$ is H, can be di-brominated to provide compound $vi$. Selective de-bromination provides the corresponding monobromo analog $vii$, which under palladium catalyzed cyclization conditions provides the desired intermediate $viii$, wherein $R^7$ is H. Alternatively a compound of formula $v$, wherein $R^7$ is other than H, can be monobrominated to provide compound $ix$. A compound of formula $ix$ can then undergo under palladium catalyzed cyclization conditions provides the desired intermediate $x$, wherein $R^7$ is other than H.

Scheme 3 illustrates methods by which intermediate compounds of formula $xi$ can be further derivatized to provide the 2,3-Substituted Indole Derivatives, which are intermediates to the title 2,3-Substituted Indole Derivatives.

Scheme 3
wherein $R_1, R_3, R_4, R_7$ and $R_{10}$ are defined above for the compounds of formula (I); $PG$ is a carboxy protecting group; and $X$ is halo, -O-triflate, -B(alkyl)$_2$OH, -Sn(alkyl)$_3$, -MgBr, -MgCl, -ZnBr, or -ZnCl; and $M$ is any metal which can participate in an organometallic cross-coupling reaction.

An intermediate compound of formula xi can be converted to a 3-substituted indole of formula xii using methods well-known to one skilled in the art of organic synthesis. A compound of formula xii, wherein $X$ is halo or -O-triflate can then be coupled with an appropriate compound of formula $R^3$-$M$ (wherein $M$ is -B(alkyl)$_2$OH, -Si(alkyl)$_2$OH, -Sn(alkyl)$_3$, -MgBr, -MgCl, -ZnBr, -ZnCl, or any metal which can participate in an organometallic cross-coupling reaction) using an organometallic cross-coupling method. Alternatively, a compound of formula xii, wherein $X$ is -B(alkyl)$_2$OH, -Si(alkyl)$_2$OH, -Sn(alkyl)$_3$, -MgBr, -MgCl, -ZnBr, -ZnCl, or any metal which can participate in an organometallic cross-coupling reaction, can then be coupled with an appropriate compound of formula $R^3$-$M$ (wherein $M$ is halo or -O-triflate) using an organometallic cross-coupling method. Suitable cross-coupling methods include, but not limited to, a Stille coupling (see Choshi et al., J. Org. Chem., 62:2535-2543 (1997), and Scott et al., J. Am. Chem. Soc., 106:4630 (1984)), a Suzuki coupling (see Miyaura et al., Chem. Rev., 95:2457 (1995)), a Negishi coupling (see Zhou et al., J. Am. Chem. Soc., 127:12537-12530 (2003)), a silanoate-based coupling (see Denmark et al., Chem. Eur. J., 12:4954-4963 (2006)) and a Kumada coupling (see Kumada, Pure Appl. Chem., 52:669 (1980) and Fu et al, Angew. Chem. 114:4363 (2002)) to provide a compound of formula $F$. The carboxy protecting group, $PG$, can then be removed from the compound of formula xiv and the
resulting carboxylic acid can be derivatized using the methods described below in order to make the appropriate \( R^2 \) groups and make the compounds of formula \( xv \), which correspond to the compounds of formula (I), wherein \( R^2 \) is \(-C(O)OH\). Alternatively, a compound of formula \( xii \) can first be deprotected and the \( R^2 \) group attached using the above methods to provide a compound of formula \( xiii \). A compound of formula \( xi\) can then be cross-coupled with a compound of \( R^3\)-X or \( R^3\)-M as described above to provide the compounds of formula \( xv \).

Scheme 4 shows a method useful for making the 2,3-Substituted Indole Derivatives, wherein \( R^2 \) is \(-C(O)N(R^9)SO_2R^n\).

Scheme 5 shows a method useful for making the 2,3-Substituted Indole Derivatives,

wherein \( R^1, R^2, R^3, R^4, R^5, R^6, R^7, R^{10}, \ldots \) etc. and \( G \) are as defined for the 2,3-Substituted Indole Derivatives.

A 2-carboxy indole compound of formula \( xv \) can be coupled with a compound of formula \( R^{11}SO_2NH(R^9) \) in the presence of carbonyldiimidazole (CDI) and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) to provide the compounds of formula \( xvi \), which correspond to the 2,3-Substituted Indole Derivatives wherein \( R^2 \) is \(-C(O)NHSO_2R^{11}\).

Scheme 5 shows a method useful for making the 2,3-Substituted Indole Derivatives,
wherein $R_1$, $R_2$, $R_3$, $R_4$, $R_5$, $R_6$, $R_7$, $R_8$, $R_9$, and $R_{10}$ are defined above for the compounds of formulas (I) and (D).

A 2-carboxy indole compound of formula $\text{XV}$ can be reacted with a 2-amino sulfonamide to provide the compounds of formula $\text{XVII}$, which correspond to the 2,3-Substituted Indole Derivatives wherein $R_2$ is:

![Diagram of 2,3-Substituted Indole Derivatives]

Scheme 6 shows a method useful for making the 2,3-Substituted Indole Derivatives, wherein $R_3$ is 1H-pyridin-2-one-3-yl.

A 3-iodoindole compound of formula $\text{XVIII}$ can be coupled with 2-hydroxypyridine-3-boronic acid using a Suzuki coupling reaction to provide the $R_3$-substituted indole compounds of formula $\text{XIX}$. A compound of formula $\text{XIX}$ can be further elaborated using methods set forth above in Schemes 1-6 to provide the compounds of formula $\text{XX}$. The 2-hydroxypyridyl moiety...
of a compound of formula \( xx \) can then be reacted with strong acid, such as hydrochloric acid to provide the compounds of formula \( xxi \), which correspond to the 2,3-Substituted Indole Derivatives, wherein \( R^3 \) is \( 1H \)-pyridin-2-one-3-yl.

The starting material and reagents depicted in Schemes 1-6 are either available from commercial suppliers such as Sigma-Aldrich (St. Louis, MO) and Acros Organics Co. (Fair Lawn, NJ), or can be prepared using methods well-known to those of skill in the art of organic synthesis.

One skilled in the art will recognize that the synthesis of 2,3-Substituted Indole Derivatives may require the need for the protection of certain functional groups (\( i.e., \) derivatization for the purpose of chemical compatibility with a particular reaction condition). Suitable protecting groups for the various functional groups of the 2,3-Substituted Indole Derivatives and methods for their installation and removal may be found in Greene \( et \) al., *Protective Groups in Organic Synthesis*, Wiley-Interscience, New York, (1999).

One skilled in the art will recognize that one route will be optimal depending on the choice of appendage substituents. Additionally, one skilled in the art will recognize that in some cases the order of steps has to be controlled to avoid functional group incompatibilities. One skilled in the art will recognize that a more convergent route (\( i.e. \) non-linear or preassembly of certain portions of the molecule) is a more efficient method of assembly of the target compounds. Methods suitable for the preparation of 2,3-Substituted Indole Derivatives are set forth above in Schemes 1-6.

The starting materials and the intermediates prepared using the methods set forth in Schemes 1-6 may be isolated and purified if desired using conventional techniques, including but not limited to filtration, distillation, crystallization, chromatography and the like. Such materials can be characterized using conventional means, including physical constants and spectral data.

**EXAMPLES**

**General Methods**

Solvents, reagents, and intermediates that are commercially available were used as received. Reagents and intermediates that are not commercially available were prepared in the manner as described below. \(^1H\) NMR spectra were obtained on a Bruker Avance 500 (500 MHz) and are reported as ppm down field from Me_4Si with number of protons, multiplicities,

The mixture was allowed to stir at room temp and eventually became a homogeneous solution (after 15 min). TLC (30% ethyl acetate in hexanes) showed complete consumption of starting material after 20 minutes. The reaction was quenched by addition of 5 drops of aq. 1M HCl and further diluted with 5 mL of DMF. The solution was injected into an semi-prep HPLC system under the following conditions: Delta Pak Column, C18, 5 micrometer, 300A; 300 x 30 mm I.D.; Flow rate: 30 mL/min; Gradient: 40% acetonitrile (0.01% TFA) in water (0.01% TFA) for 10 min then increase to 90% over 20 min and stay for 10 minutes. Example 41

HCV NS5B Polymerase Inhibition Assay

An in vitro transcribed heteropolymeric RNA known as D-RNA or DCoH has been shown to be an efficient template for HCV NS5B polymerase (S.-E. Behrens et al., EMBO J. 15:12-22 (1996); WO 96/37619). A chemically synthesized 75-mer version, designated DCoH75, whose sequence matches the 3'-end of D-RNA, and DCoH75ddC, where the 3'-terminal cytidine of DCoH75 is replaced by dideoxycytidine, were used for assaying the NS5B
enzyme activity as described in Ferrari et al., 12th International Symposium on HCV and Related Viruses, P-306 (2005). A soluble C-terminal 21-amino acid truncated NS5B enzyme form (NS5BDeltaCT21) was produced and purified from Escherichia coli as C-terminal polyhistidine-tagged fusion protein as described in Ferrari et al., J. Virol. 73:1649-1654 (1999). A typical assay contained 20 mM Hepes pH 7.3, 10 mM MgCl₂, 60 mM NaCl, 100 μg/ml BSA, 20 units/ml RNasin, 7.5 mM DTT, 0.1 mM ATP/GTP/UTP, 0.026 μM CTP, 0.25 mM GAU, 0.03 μM RNA template, 20 μCi/ml [³²P]-CTP, 2% DMSO, and 30 or 150 nM NS5B enzyme. Reactions were incubated at 22 °C for 2 hours, then stopped by adding 150 mM EDTA, washed in DE81 filter plate in 0.5M di-basic sodium phosphate buffer, pH 7.0, and counted using Packard TopCount after the addition of scintillation cocktail. Polynucleotide synthesis was monitored by the incorporation of radiolabeled CTP. The effect of the 2,3-Substituted Indole Derivatives on the polymerase activity was evaluated by adding various concentrations of a 2,3-Substituted Indole Derivative, typically in 10 serial 2-fold dilutions, to the assay mixture. The starting concentrations of the indole derivatives ranged from 200 μM to 1 μM. An IC₅₀ value for the inhibitor, defined as the compound concentration that provides 50% inhibition of polymerase activity, was determined by fitting the cpm data to the Hill equation Y=100/(1+10⁻⁴*(LogIC₅₀-X)*HillSlope), where X is the logarithm of compound concentration, and Y is the % inhibition. Ferrari et al., 12th International Symposium on HCV and Related Viruses, P-306 (2005) described in detail this assay procedure. It should be noted that such an assay as described is exemplary and not intended to limit the scope of the invention. The skilled practitioner can appreciate that modifications including but not limited to RNA template, primer, nucleotides, NS5B polymerase form, buffer composition, can be made to develop similar assays that yield the same result for the efficacy of the compounds and compositions described in the invention.

NS5B polymerase inhibition data for selected 2,3-Substituted Indole Derivatives of the present invention was obtained using the above method and calculated IC₅₀ values ranged from about 0.001 μM to about 14000 μM.

**Example 42**

**Cell-based HCV Replicon Assay**

To measure cell-based anti-HCV activity of the 2,3-Substituted Indole Derivatives of the present invention, replicon cells were seeded at 5000 cells/well in 96-well collagen I-coated
Nunc plates in the presence of the 2,3-Substituted Indole Derivative. Various concentrations of a 2,3-Substituted Indole Derivative, typically in 10 serial 2-fold dilutions, were added to the assay mixture, the starting concentration of the compound ranging from 250 μM to 1 μM. The final concentration of DMSO was 0.5%, fetal bovine serum was 5%, in the assay media. Cells were harvested on day 3 by the addition of 1x cell lysis buffer (Ambion cat #8721). The replicon RNA level was measured using real time PCR (Taqman assay). The amplicon was located in 5B. The PCR primers were: 5B.2F, ATGGACAGGCGCCTGA; 5B.2R, TTGATGGCAGCTTGGTTTC; the probe sequence was FAM-labeled CACGCCATGCCTGCGG. GAPDH RNA was used as endogenous control and was amplified in the same reaction as NS5B (multiplex PCR) using primers and VIC-labeled probe recommended by the manufacturer (PE Applied Biosystem). The real-time RT-PCR reactions were run on ABI PRISM 7900HT Sequence Detection System using the following program: 48°C for 30 minutes, 95°C for 10 minutes, 40 cycles of 95°C for 15 sec, 60°C for 1 minute. The ΔCT values (CT_{5B-NS5B}-CT_{GAPDH}) were plotted against the concentration of test compound and fitted to the sigmoid dose-response model using XLfit4 (MDL). EC_{50} was defined as the concentration of inhibitor necessary to achieve ΔCT=1 over the projected baseline; EC_{90} the concentration necessary to achieve ΔCT=3.2 over the baseline. Alternatively, to quantitate the absolute amount of replicon RNA, a standard curve was established by including serially diluted T7 transcripts of replicon RNA in the Taqman assay. All Taqman reagents were from PE Applied Biosystems. Such an assay procedure was described in detail in e.g. Malcolm et al, *Antimicrobial Agents and Chemotherapy* 50: 1013-1020 (2006).

HCV Replicon assay data for selected 2,3-Substituted Indole Derivatives of the present invention was obtained using the above method and calculated EC_{50} values ranged from about 1 μM to about 14000 μM.

Additional genotypes 7-10 and 11 have been proposed, however the phylogenetic basis on which this classification is based has been questioned, and thus types 7, 8, 9 and 11 isolates have been reassigned as type 6, and type 10 isolates as type 3 (see Lamballerie et al, *J Gen Virol*, 78(Ttl):45-51 (1997)). The major genotypes have been defined as having sequence similarities of between 55 and 72% (mean 64.5%), and subtypes within types as having 75%-86% similarity (mean 80%) when sequenced in the NS-5 region (see Simmonds et al, *J Gen Virol* 75(Tt 5):1053-1061 (1994)).

Accordingly, in one embodiment, the present invention provides methods for treating a viral infection in a patient, the method comprising administering to the patient: (i) at least one 2,3-Substituted Indole Derivative, or a pharmaceutically acceptable salt, solvate, ester or prodrug thereof, and (ii) at least one other antiviral agent that is other than a 2,3-Substituted Indole Derivative, wherein the amounts administered are together effective to treat or prevent a viral infection.

When administering a combination therapy of the invention to a patient, the therapeutic agents in the combination, or a pharmaceutical composition or compositions comprising the therapeutic agents, may be administered in any order such as, for example, sequentially, concurrently, together, simultaneously and the like. The amounts of the various actives in such combination therapy may be different amounts (different dosage amounts) or same amounts (same dosage amounts). Thus, for non-limiting illustration purposes, a 2,3-Substituted Indole Derivative and an additional therapeutic agent may be present in fixed amounts (dosage amounts) in a single dosage unit (e.g., a capsule, a tablet and the like). A commercial example of such single dosage unit containing fixed amounts of two different active compounds is VYTORIN® (available from Merck Schering-Plough Pharmaceuticals, Kenilworth, New Jersey).

In one embodiment, the at least one 2,3-Substituted Indole Derivative is administered during at time when the additional antiviral agent(s) exert their prophylactic or therapeutic effect, or vice versa.

In another embodiment, the at least one 2,3-Substituted Indole Derivative and the additional antiviral agent(s) are administered in doses commonly employed when such agents are used as monotherapy for treating a viral infection.

In another embodiment, the at least one 2,3-Substituted Indole Derivative and the additional antiviral agent(s) are administered in doses lower than the doses commonly employed when such agents are used as monotherapy for treating a viral infection.

In still another embodiment, the at least one 2,3-Substituted Indole Derivative and the additional antiviral agent(s) act synergistically and are administered in doses lower than the doses commonly employed when such agents are used as monotherapy for treating a viral infection.
In one embodiment, the at least one 2,3-Substituted Indole Derivative and the additional antiviral agent(s) are present in the same composition. In one embodiment, this composition is suitable for oral administration. In another embodiment, this composition is suitable for intravenous administration.

Viral infections and virus-related disorders that can be treated or prevented using the combination therapy methods of the present invention include, but are not limited to, those listed above.

In one embodiment, the viral infection is HCV infection.

The at least one 2,3-Substituted Indole Derivative and the additional antiviral agent(s) can act additively or synergistically. A synergistic combination may allow the use of lower dosages of one or more agents and/or less frequent administration of one or more agents of a combination therapy. A lower dosage or less frequent administration of one or more agents may lower toxicity of the therapy without reducing the efficacy of the therapy.

In one embodiment, the administration of at least one 2,3-Substituted Indole Derivative and the additional antiviral agent(s) may inhibit the resistance of a viral infection to these agents.

**Compositions and Administration**

Due to their activity, the 2,3-Substituted Indole Derivatives are useful in veterinary and
human medicine. As described above, the 2,3-Substituted Indole Derivatives are useful for treating or preventing a viral infection or a virus-related disorder in a patient in need thereof.

When administered to a patient, the IDs can be administered as a component of a composition that comprises a pharmaceutically acceptable carrier or vehicle. The present invention provides pharmaceutical compositions comprising an effective amount of at least one 2,3-Substituted Indole Derivative and a pharmaceutically acceptable carrier. In the pharmaceutical compositions and methods of the present invention, the active ingredients will typically be administered in admixture with suitable carrier materials suitably selected with respect to the intended form of administration, i.e. oral tablets, capsules (either solid-filled, semi-solid filled or liquid filled), powders for constitution, oral gels, elixirs, dispersible granules, syrups, suspensions, and the like, and consistent with conventional pharmaceutical practices. For example, for oral administration in the form of tablets or capsules, the active drug component may be combined with any oral non-toxic pharmaceutically acceptable inert carrier, such as lactose, starch, sucrose, cellulose, magnesium stearate, dicalcium phosphate, calcium sulfate, talc, mannitol, ethyl alcohol (liquid forms) and the like. Solid form preparations include powders, tablets, dispersible granules, capsules, cachets and suppositories. Powders and tablets may be comprised of from about 5 to about 95 percent inventive composition. Tablets, powders, cachets and capsules can be used as solid dosage forms suitable for oral administration.

Moreover, when desired or needed, suitable binders, lubricants, disintegrating agents and coloring agents may also be incorporated in the mixture. Suitable binders include starch, gelatin, natural sugars, corn sweeteners, natural and synthetic gums such as acacia, sodium alginate, carboxymethylcellulose, polyethylene glycol and waxes. Among the lubricants there may be mentioned for use in these dosage forms, boric acid, sodium benzoate, sodium acetate, sodium chloride, and the like. Disintegrants include starch, methylcellulose, guar gum and the like. Sweetening and flavoring agents and preservatives may also be included where appropriate.

Liquid form preparations include solutions, suspensions and emulsions and may include water or water-propylene glycol solutions for parenteral injection.

Liquid form preparations may also include solutions for intranasal administration.
Aerosol preparations suitable for inhalation may include solutions and solids in powder form, which may be in combination with a pharmaceutically acceptable carrier, such as an inert compressed gas. Also included are solid form preparations which are intended to be converted, shortly before use, to liquid form preparations for either oral or parenteral administration. Such liquid forms include solutions, suspensions and emulsions.

For preparing suppositories, a low melting wax such as a mixture of fatty acid glycerides or cocoa butter is first melted, and the active ingredient is dispersed homogeneously therein as by stirring. The molten homogeneous mixture is then poured into convenient sized molds, allowed to cool and thereby solidify.

The 2,3-Substituted Indole Derivatives of the present invention may also be deliverable transdermally. The transdermal compositions can take the form of creams, lotions, aerosols and/or emulsions and can be included in a transdermal patch of the matrix or reservoir type as are conventional in the art for this purpose.

Additionally, the compositions of the present invention may be formulated in sustained release form to provide the rate controlled release of any one or more of the components or active ingredients to optimize the therapeutic effects, i.e. anti-inflammatory activity and the like. Suitable dosage forms for sustained release include layered tablets containing layers of varying disintegration rates or controlled release polymeric matrices impregnated with the active components and shaped in tablet form or capsules containing such impregnated or encapsulated porous polymeric matrices.

In various embodiments, the present compositions can contain, in one embodiment, from about 1% to about 70% or from about 5% to about 60% of the 2,3-Substituted Indole Derivative(s) by weight or volume.

The quantity of 2,3-Substituted Indole Derivative in a unit dose of preparation may be varied or adjusted from about 0.1 mg to about 2000 mg. In various embodiment, the quantity is from about 1 mg to about 2000 mg, 100 mg to about 200 mg, 500 mg to about 2000 mg, 100 mg to about 1000 mg, and 1 mg to about 500 mg.

For convenience, the total daily dosage may be divided and administered in portions during the day if desired. In one embodiment, the daily dosage is administered in one portion. In another embodiment, the total daily dosage is administered in two divided doses over a 24 hour period. In another embodiment, the total daily dosage is administered in three divided doses over a 24 hour period. In still another embodiment, the total daily dosage is administered in four divided doses over a 24 hour period.

The amount and frequency of administration of the 2,3-Substituted Indole Derivatives will be regulated according to the judgment of the attending clinician considering such factors as age, condition and size of the patient as well as severity of the symptoms being treated. Generally, a total daily dosage of the 2,3-Substituted Indole Derivatives range from about 0.1 to about 2000 mg per day, although variations will necessarily occur depending on the target of the therapy, the patient and the route of administration.
