MACROCYCLIC SERINE PROTEASE INHIBITORS

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of the priority of U.S. Provisional Application Nos. 61/026,086, filed February 4, 2008, and 61/083,867, filed July 25, 2008, the disclosure of each of which is incorporated herein by reference in its entirety.

FIELD

[0001] Provided herein are macrocyclic serine protease inhibitor compounds, pharmaceutical compositions comprising the compounds, and processes of preparation thereof. Also provided are methods of their use for the treatment of an HCV infection in a host in need thereof.

BACKGROUND

[0002] Hepatitis C virus (HCV) is known to cause at least 80% of posttransfusion hepatitis and a substantial proportion of sporadic acute hepatitis (Houghton et al., Science 1989, 244, 362-364; Thomas, Curr. Top. Microbiol. Immunol. 2000, 25-41). Preliminary evidence also implicates HCV in many cases of "idiopathic" chronic hepatitis, "cryptogenic" cirrhosis, and probably hepatocellular carcinoma unrelated to other hepatitis viruses, such as hepatitis B virus (Di Besceglie et al., Scientific American, 1999, October, 80-85; Boyer et al., J. Hepatol. 2000, 32, 98-112).

[0003] HCV is an enveloped virus containing a positive-sense single-stranded RNA genome of approximately 9.4 kb (Kato et al., Proc. Natl. Acad. Sci. USA 1990, 87, 9524-9528; Kato, Acta Medica Okayama, 2001, 55, 133-159). The viral genome consists of a 5' untranslated region (UTR), a long open reading frame encoding a polyprotein precursor of approximately 3011 amino acids, and a short 3' UTR. The 5' UTR is the most highly conserved part of the HCV genome and is important for the initiation and control of polyprotein translation. Translation of the HCV genome is initiated by a cap-independent mechanism known as an internal ribosome entry. This mechanism involves the binding of ribosomes to an RNA sequence known as the internal ribosome entry site (IRES). An RNA pseudoknot structure has recently been determined to be an essential structural element of the HCV IRES. Viral structural proteins include a nucleocapsid core protein (C) and two
envelope glycoproteins, E1 and E2. HCV also encodes two proteinases, a zinc-dependent metalloproteinase encoded by the NS2-NS3 region and a serine proteinase encoded in the NS3 region. These proteinases are required for cleavage of specific regions of the precursor polyprotein into mature peptides. The carboxyl half of nonstructural protein 5, NS5B, contains the RNA-dependent RNA polymerase. The function of the remaining nonstructural proteins, NS4A and NS4B, and that of NS5A (the amino-terminal half of nonstructural protein 5) remain unknown.

[0004] Presently, the most effective HCV therapy employs a combination of alpha-interferon and ribavirin, leading to sustained efficacy in about 40% of patients (Poynard et al., *Lancet* 1998, 352, 1426-1432). Recent clinical results demonstrate that pegylated alpha-interferon is superior to unmodified alpha-interferon as monotherapy. However, even with experimental therapeutic regimens involving combinations of pegylated alpha-interferon and ribavirin, a substantial fraction of patients do not have a sustained reduction in viral load (Manns et al, *Lancet* 2001, 358, 958-965; Fried et al., *N. Engl. J. Med.* 2002, 347, 975-982; Hadziyannis et al., *Ann. Intern. Med.* 2004, 140, 346-355). Thus, there is a clear and unmet need to develop effective therapeutics for treatment of HCV infection.

**Compounds**

[0046] HCV has a single positive-stranded RNA genome having about 9.6 kb in
length that encodes a large polyprotein having about 3010 amino acids. This precursor polyprotein is then processed into a range of structural proteins, including core protein, C, and envelope glycoproteins, E1 and E2; and non-structural proteins, including NS2, NS3, NS4A, NS4B, NS5A, and NS5B, by host signal peptidases and two viral proteases, NS2-3 and NS3. The NS3 protein contains a trypsin-like serine protease domain at its N-terminus, while its C-terminal domain has helicase activity. Because of its vital role in viral replication, HCV NS3 serine protease has been actively pursued as a drug target for developing a new anti-HCV therapy.

[0048] Provided herein are compounds which are useful for the treatment of HCV infection, which, in one embodiment, can have activity as HCV serine protease inhibitors. Also provided herein are pharmaceutical compositions that comprise the compounds, methods of manufacture of the compounds, and methods of use of the compounds for the treatment of HCV infection in a host in need of treatment.
In one embodiment, provided herein is a compound of Formula I:

The compounds provided herein are intended to encompass all possible stereoisomers, unless a particular stereochemistry is specified. Where the compound provided herein contains an alkenyl or alkenylene group, the compound may exist as one or mixture of geometric cis/trans (or Z/E) isomers. Where structural isomers are interconvertible via a low energy barrier, the compound may exist as a single tautomer or a mixture of tautomers. This can take the form of proton tautomerism in the compound that contains, for example, an imino, keto, or oxime group; or so-called valence tautomerism in the compound that contain an aromatic moiety. It follows that a single compound may exhibit more than one type of isomerism.

The heterocyclic moiety that is fused with the macrocyclic ring in the compound provided herein contains two chiral centers as indicated by star symbols. As result, the heterocyclic moiety may exist in four different stereoisomeric forms as shown.
below, including two cis isomers, (i) and (ii), and two trans isomers, (iii) and (iv).

[00135] In certain embodiments, the heterocyclic moiety in the compound provided herein is in a cis configuration, (i), (ii), or a mixture thereof. In certain embodiments, the heterocyclic moiety in the compound provided herein is in cis configuration (i). In certain embodiments, the heterocyclic moiety in the compound provided herein is in cis configuration (ii). In certain embodiments, the heterocyclic moiety in the compound provided herein is in cis configuration (i) and (ii).

[00136] In certain embodiments, the heterocyclic moiety in the compound provided herein is in a trans configuration, (iii), (iv), or a mixture thereof. In certain embodiments, the heterocyclic moiety in the compound provided herein is in trans configuration (iii). In certain embodiments, the heterocyclic moiety in the compound provided herein is in trans configuration (iv). In certain embodiments, the heterocyclic moiety in the compound provided herein is in trans configuration (iii) and (iv).

[00137] In certain embodiments, the heterocyclic moiety in the compound provided herein is in configuration (i), (iii), or a mixture thereof. In certain embodiments, the heterocyclic moiety in the compound provided herein is in configuration (i). In certain embodiments, the heterocyclic moiety in the compound provided herein is in configuration (iii). In certain embodiments, the heterocyclic moiety in the compound provided herein is in configuration (i) and (iii).

[00138] In certain embodiments, the heterocyclic moiety in the compound provided herein is in configuration (ii), (iv), or a mixture thereof. In certain embodiments, the heterocyclic moiety in the compound provided herein is in configuration (ii). In certain embodiments, the heterocyclic moiety in the compound provided herein is in configuration (iv). In certain embodiments, the heterocyclic moiety in the compound provided herein is in configuration (ii) and (iv).

[00139] The heterocyclic moiety of a particular configuration can readily be introduced
by selecting a chiral starting material that will yield the desired chirality. For example, various chiral 4-hydroxyl prolines are available commercially, including cw-4-hydroxy-D-proline, cw-4-hydroxy-L-proline, and tr<ms-4-L-proline.

[00140] The compounds provided herein may be enantiomerically pure, such as a single enantiomer or a single diastereomer, or be stereoisomeric mixtures, such as a racemic mixture or a diastereomeric mixture. As such, one of skill in the art will recognize that administration of a compound in its (R) form is equivalent, for compounds that undergo epimerization in vivo, to administration of the compound in its (S) form. Conventional techniques for the preparation/isolation of individual enantiomers include synthesis from a suitable optically pure precursor, asymmetric synthesis from achiral starting materials, or resolution of an enantiomeric mixture, for example, chiral chromatography, recrystallization, resolution, diastereomeric salt formation, or derivatization into diastereomeric adducts followed by separation.

Methods of Synthesis

[00145] The compound provided herein can be prepared, isolated, or obtained by any method known to one of skill in the art. For an example, a compound of Formula I can be prepared as shown in Scheme 1.

[00146] N-Protected 4-hydroxyproline 1 with a desired stereochemistry is coupled with an amine with a terminal carbon-carbon double bond to form amide 2. Compound 2 is then converted into a free amine by removing the N-protecting group on its proline moiety with a Lewis acid, such as trifluoroacetic acid, followed by coupling with a cyclopropylamine to yield compound 3, which is then protected with a hydroxyl protecting group, such as TBDMSCl, and cyclized in the presence of a metathesis catalyst to yield macrocyclic compound 4. The hydroxyl protecting group of compound 4 is removed to yield compound 5 with a free hydroxyl group. At this point, a variety of R6-L group can be introduced at the hydroxyl position using various chemistries, such as coupling reactions to form ester, carboxylate, or carbamate with the hydroxyl group, or nucleophilic substitution reactions to form ether, amine, or thioether. A nucleophilic substitution reaction to form an ether linkage is illustrated in Scheme 1. Compound 5 reacts with R6OH under Mitsunobu condition with inversion of the stereochemistry at the position of the hydroxyl group to produce compound 6 with oxy as L in Formula I as provided herein. The ethyl protecting group is removed from the carboxyl group of compound 6 to yield a free acid, which is readily coupled with a variety of amines to form desired macrocyclic serine protease inhibitors, such as sulfonamide 7.
An alternative strategy is shown in Scheme 2, where double inversion of the stereochemistry at the position of the hydroxyl group is employed to retain its original stereochemistry. Compound 5 is first converted into para-nitrobenzoyl (PNB) ester 8 under Mitsunobu condition with the first inversion of the stereochemistry at the position of the hydroxyl group. The PNB ester 8 is hydrolyzed, and then reacts with R⁶OH under Mitsunobu condition with the second inversion of the stereochemistry at the position of the hydroxyl group to yield compound 10 with retention of its original stereochemistry at the position of hydroxyl group.

The starting materials used in the synthesis of the compounds provided herein are either commercially available or can be readily prepared. For example, beta amino
sulfonamide is synthesized as shown in Scheme 3 and quinoline derivatives are synthesized as shown in Scheme 4, wherein A, R^5, R^6, R^7, and R^8 are as defined herein.

Scheme 2

Scheme 3

The chloro at the 4 position of compound 119 is then converted to hydroxylin in the presence of a base, including, but not limited to, NaOH, KOH, KOAc, and NaOAc.

The pharmaceutical compositions provided herein in a modified release dosage form may be prepared by methods known to those skilled in the art, including direct compression, dry or wet granulation followed by compression, melt-granulation followed by compression.

2. Osmotic Controlled Release Devices

The pharmaceutical compositions provided herein in a modified release dosage form may be fabricated using an osmotic controlled release device, including one-chamber system, two-chamber system, asymmetric membrane technology (AMT), and extruding core system (ECS). In general, such devices have at least two components: (a) the core which contains the active ingredient(s); and (b) a semipermeable membrane with at least one delivery port, which encapsulates the core. The semipermeable membrane controls the influx of water to the core from an aqueous environment of use so as to cause drug release by extrusion through the delivery port(s).

In addition to the active ingredient(s), the core of the osmotic device optionally includes an osmotic agent, which creates a driving force for transport of water from the environment of use into the core of the device. One class of osmotic agents water-swellable hydrophilic polymers, which are also referred to as "osmopolymers" and "hydrogels," including, but not limited to, hydrophilic vinyl and acrylic polymers, polysaccharides such as calcium alginate, polyethylene oxide (PEO), polyethylene glycol (PEG), polypropylene glycol (PPG), poly(2-hydroxyethyl methacrylate), poly(acrylic) acid, poly(methacrylic) acid, polyvinylpyrrolidone (PVP), crosslinked PVP, polyvinyl alcohol (PVA), PVA/PVP copolymers, PVA/PVP copolymers with hydrophobic monomers such as methyl methacrylate and vinyl acetate, hydrophilic polyurethanes containing large PEO blocks, sodium croscarmellose, carrageenan, hydroxyethyl cellulose (HEC), hydroxypropyl cellulose (HPC), hydroxypropyl methyl cellulose (HPMC), carboxymethyl cellulose (CMC) and carboxyethyl, cellulose (CEC), sodium alginate, polycarbophil, gelatin, xanthan gum, and sodium starch glycolate.

The other class of osmotic agents is osmogens, which are capable of imbibing
water to affect an osmotic pressure gradient across the barrier of the surrounding coating. Suitable osmogens include, but are not limited to, inorganic salts, such as magnesium sulfate, magnesium chloride, calcium chloride, sodium chloride, lithium chloride, potassium sulfate, potassium phosphates, sodium carbonate, sodium sulfite, lithium sulfate, potassium chloride, and sodium sulfate; sugars, such as dextrose, fructose, glucose, inositol, lactose, maltose, mannitol, raffinose, sorbitol, sucrose, trehalose, and xylitol.; organic acids, such as ascorbic acid, benzoic acid, fumaric acid, citric acid, maleic acid, sebacic acid, sorbic acid, adipic acid, edetic acid, glutamic acid, p-toluenesulfonic acid, succinic acid, and tartaric acid; urea; and mixtures thereof.

[00216] Osmotic agents of different dissolution rates may be employed to influence how rapidly the active ingredient(s) is initially delivered from the dosage form. For example, amorphous sugars, such as MANNOGEM™ EZ (SPI Pharma, Lewes, DE) can be used to provide faster delivery during the first couple of hours to promptly produce the desired therapeutic effect, and gradually and continually release of the remaining amount to maintain the desired level of therapeutic or prophylactic effect over an extended period of time. In this case, the active ingredient(s) is released at such a rate to replace the amount of the active ingredient metabolized and excreted.

[00217] The core may also include a wide variety of other excipients and carriers as described herein to enhance the performance of the dosage form or to promote stability or processing.

[00218] Materials useful in forming the semipermeable membrane include various grades of acrylcs, vins, ethers, polyamides, polyesters, and cellulosic derivatives that are water-permeable and water-insoluble at physiologically relevant pHs, or are susceptible to being rendered water-insoluble by chemical alteration, such as crosslinking. Examples of suitable polymers useful in forming the coating, include plasticized, unplasticized, and reinforced cellulose acetate (CA), cellulose diacetate, cellulose triacetate, CA propionate, cellulose nitrate, cellulose acetate butyrate (CAB), CA ethyl carbamate, CAP, CA methyl carbamate, CA succinate, cellulose acetate trimellitate (CAT), CA dimethylaminoacetate, CA ethyl carbonate, CA chloroacetate, CA ethyl oxalate, CA methyl sulfonate, CA butyl sulfonate, CA p-toluene sulfonate, agar acetate, amylose triacetate, beta glucan acetate, beta glucan triacetate, acetaldehyde dimethyl acetate, triacetate of locust bean gum, hydroxylated ethylene-vinylacetate, EC, PEG, PPG, PEG/PPG copolymers, PVP, HEC, HPC, CMC,
CMEC, HPMC, HPMCP, HPMCAS, HPMCAT, poly(acrylic) acids and esters and poly-(methacrylic) acids and esters and copolymers thereof, starch, dextran, dextrin, chitosan, collagen, gelatin, polyalkenes, polyethers, polysulfones, polyethersulfones, polystyrenes, polyvinyl halides, polyvinyl esters and others, natural waxes, and synthetic waxes.

In certain embodiments, the pharmaceutical compositions provided herein are conventional dosage forms, wherein the active ingredient(s) are released at a predictable rate. The active ingredient(s) may be released through a semipermeable membrane, wherein the pores are substantially filled with a gas and are not wetted by the aqueous medium but are permeable to water vapor, as disclosed in U.S. Pat. No. 5,798,119. Such hydrophobic but water-vapor permeable membrane are typically composed of hydrophobic polymers such as polyalkenes, polyethylene, polypropylene, polytetrafluoroethylene, polyacrylic acid derivatives, polyethers, polysulfones, polyethersulfones, polystyrenes, polyvinyl halides, polyvinylidene fluoride, polyvinyl esters and others, natural waxes, and synthetic waxes.

The delivery port(s) on the semipermeable membrane may be formed post-coating by mechanical or laser drilling. Delivery port(s) may also be formed in situ by erosion of a plug of water-soluble material or by rupture of a thinner portion of the membrane over an indentation in the core. In addition, delivery ports may be formed during coating process, as in the case of asymmetric membrane coatings of the type disclosed in U.S. Pat. Nos. 5,612,059 and 5,698,220.

The total amount of the active ingredient(s) released and the release rate can substantially by modulated via the thickness and porosity of the semipermeable membrane, the composition of the core, and the number, size, and position of the delivery ports.

The pharmaceutical compositions in an osmotic controlled-release dosage form may further comprise additional conventional excipients or carriers as described herein to promote performance or processing of the formulation.

The osmotic controlled-release dosage forms can be prepared according to conventional methods and techniques known to those skilled in the art (see, Remington: The Science and Practice of Pharmacy, supra; Santus and Baker, J Controlled Release 1995, 35, 1-21; Verma et al., Drug Development and Industrial Pharmacy 2000, 26, 695-708; Verma et al., J Controlled Release 2002, 79, 7-27).

In certain embodiments, the pharmaceutical compositions provided herein are...
formulated as AMT controlled-release dosage form, which comprises an asymmetric osmotic membrane that coats a core comprising the active ingredient(s) and other pharmaceutically acceptable excipients or carriers. See, U.S. Pat. No. 5,612,059 and WO 2002/17918. The AMT controlled-release dosage forms can be prepared according to conventional methods and techniques known to those skilled in the art, including direct compression, dry granulation, wet granulation, and a dip-coating method.

[00225] In certain embodiments, the pharmaceutical compositions provided herein are formulated as ESC controlled-release dosage form, which comprises an osmotic membrane that coats a core comprising the active ingredient(s), a hydroxylethyl cellulose, and other pharmaceutically acceptable excipients or carriers.

[00226] The pharmaceutical compositions provided herein in a modified release dosage form may be fabricated a multiparticulate controlled release device, which comprises a multiplicity of particles, granules, or pellets, ranging from about 10 μm to about 3 mm, about 50 μm to about 2.5 mm, or from about 100 μm to about 1 mm in diameter. Such multiparticulates may be made by the processes know to those skilled in the art, including wet-and dry-granulation, extrusion/spheronization, roller-compaction, melt-congealing, and by spray-coating seed cores. See, for example, Multiparticulate Oral Drug Delivery; Marcel Dekker: 1994; and Pharmaceutical Peptization Technology; Marcel Dekker: 1989.

[00227] Other excipients or carriers as described herein may be blended with the pharmaceutical compositions to aid in processing and forming the multiparticulates. The resulting particles may themselves constitute the multiparticulate device or may be coated by various film-forming materials, such as enteric polymers, water-swellable, and water-soluble polymers. The multiparticulates can be further processed as a capsule or a tablet.

Combination Therapy

[00243] The compounds provided herein may also be combined or used in combination with other therapeutic agents useful in the treatment and/or prevention of an HCV infection.

[00244] As used herein, the term "in combination" includes the use of more than one therapy (e.g., one or more prophylactic and/or therapeutic agents). However, the use of the term "in combination" does not restrict the order in which therapies (e.g., prophylactic and/or therapeutic agents) are administered to a subject with a disease or disorder. A first therapy (e.g., a prophylactic or therapeutic agent such as a compound provided herein) can be administered prior to (e.g., 5 minutes, 15 minutes, 30 minutes, 45 minutes, 1 hour, 2 hours, 4 hours, 6 hours, 12 hours, 24 hours, 48 hours, 72 hours, 96 hours, 1 week, 2 weeks, 3 weeks, 4 weeks, 5 weeks, 6 weeks, 8 weeks, or 12 weeks before), concomitantly with, or subsequent to (e.g., 5 minutes, 15 minutes, 30 minutes, 45 minutes, 1 hour, 2 hours, 4 hours, 6 hours, 12 hours, 24 hours, 48 hours, 72 hours, 96 hours, 1 week, 2 weeks, 3 weeks, 4 weeks, 5 weeks, 6 weeks, 8 weeks, or 12 weeks after) the administration of a second therapy (e.g., a prophylactic or therapeutic agent) to the subject. Triple therapy is also contemplated herein.

[00245] As used herein, the term "synergistic" includes a combination of a compound provided herein and another therapy (e.g., a prophylactic or therapeutic agent) which has been or is currently being used to treat, prevent, or manage a disease or disorder, which is more effective than the additive effects of the therapies. A synergistic effect of a combination of therapies (e.g., a combination of prophylactic or therapeutic agents) permits the use of lower dosages of one or more of the therapies and/or less frequent administration of said therapies to a subject with a disorder. The ability to utilize lower dosages of a therapy (e.g., a prophylactic or therapeutic agent) and/or to administer said therapy less frequently reduces the toxicity associated with the administration of said therapy to a subject without reducing the efficacy of said therapy in the prevention or treatment of a disorder). In addition, a synergistic effect can result in improved efficacy of agents in the prevention or treatment of a disorder. Finally, a synergistic effect of a combination of therapies (e.g., a combination of prophylactic or therapeutic agents) may avoid or reduce adverse or unwanted side effects associated with the use of either therapy alone.

[00246] The compound provided herein can be administered in combination or
alteration with another therapeutic agent, such as an anti-HCV agent. In combination therapy, effective dosages of two or more agents are administered together, whereas in alternation or sequential-step therapy, an effective dosage of each agent is administered serially or sequentially. The dosages given will depend on absorption, inactivation and excretion rates of the drug as well as other factors known to those of skill in the art. It is to be noted that dosage values will also vary with the severity of the condition to be alleviated. It is to be further understood that for any particular subject, specific dosage regimens and schedules should be adjusted over time according to the individual need and the professional judgment of the person administering or supervising the administration of the compositions.

[00247] It has been recognized that drug-resistant variants of HCV can emerge after prolonged treatment with an antiviral agent. Drug resistance most typically occurs due to the mutation of a gene that encodes for an enzyme used in viral replication. The efficacy of a drug against the viral infection can be prolonged, augmented, or restored by administering the compound in combination or alternation with a second, and perhaps third, antiviral compound that induces a different mutation from that caused by the principle drug. Alternatively, the pharmacokinetics, biodistribution or other parameters of the drug can be altered by such combination or alternation therapy. In general, combination therapy is typically preferred over alternation therapy because it induces multiple simultaneous stresses on the virus.

Synthesis of DArPhin Catalysts

[00560] The DArPhin catalysts, such as AP, AQ, AR, and AT, were prepared
following methods described herein as shown in Scheme 36.
**Step A**: Synthesis of 5-bromo-2-isopropoxybenzaldehyde AX. To a suspension of potassium carbonate (34.4 g, 249 mmol) and cesium carbonate (16.2 g, 50 mmol) in dimethylformamide were added 5-bromosalicaldehyde (25.0 g, 124 mmol) and 2-iodopropane (25.0 mL, 249 mmol). The suspension was stirred at room temperature overnight, then at 70 °C for 4 hrs. The volatiles were removed, and the residue was partitioned between methyl t-butylether and water. The aqueous layer was extracted with methyl t-butylether and the combined organic phases were washed with water, sodium hydroxide, and brine, and then dried over magnesium sulfate. Concentration to dryness afforded compound AX (30.0 g) as a pale yellow oil in 99% yield.

$^1$H NMR (CDCl$_3$, 400 MHz): δ 1.40 (d, $J = 6.3$ Hz, 6H), 4.65 (sept., $J = 6.0$ Hz, 1H), 6.89 (d, $J = 9.0$ Hz, 1H), 7.59 (dd, $J = 9.0$ and 2.7 Hz, 1H), 7.91 (d, $J = 2.7$ Hz, 1H), 10.39 (s, 1H).

**Step B**: Synthesis of 4-bromo-l-isopropoxy-2-vinylbenzene AY. To a suspension of methyltriphenylphosphonium bromide (41.1 g, 115 mmol) in THF (1.2 L) cooled to -70 °C, was added t-butyllithium (123 mmol, 2.5 M in hexanes). The mixture was stirred for a further 10 min, and then allowed to warm up to 0 °C and stir at this temperature
for 10 min. The reaction mixture is then cooled again at -50 °C, and 5-bromo-2-isopropoxybenzaldehyde (20.0 g, 82.2 mmol) in solution in THF (5 mL) was added. The mixture was stirred for 10 min, then allowed to warm up to room temperature. An ammonium chloride solution was added and the reaction mixture was diluted with a mixture of methyl /-butylether/hexane, filtered through celite, and then dried over magnesium sulfate. The solvent was removed in vacuo to afford compound AY (18.9g) as a pale yellow oil in 95% yield.

**Ring Closure Metathesis**

[00582] All reactions were performed in 1,2-dichloroethane at 0.005 M with N\(_2\) bubbling through the reaction mixture. For the substrates depicted in Scheme 38, the typical scale of the reaction was 200-250 mg. The catalyst was added in solution in 0.5 mL of DCE, in the pre-heated reaction mixture. The conversion of the starting material was followed via
TLC and/or HPLC. Products are isolated after flash chromatography (note: compound BJ
was stirred with charcoal and filtered on celite prior to purification).

[00583] The experimental results of catalytic activity for the different catalysts are
listed in Tables 1 to 4, respectively.

Example 31
HCV Protease Assay

[00588] General procedure: Measurement of the inhibitory effect of compounds on HCV protease activity was performed with the SensoLyte™ 620 HCV Protease Assay kit from AnaSpec, Inc. (San Jose, CA) under conditions described by the supplier using 1.2 nM HCV NS3-NS4A protease, which was obtained according to Taremi et al. (Protein Science, 1998, 7, 2143-2149). The compounds were tested at a variety of concentrations in assay buffer containing a final DMSO concentration of 5%. Reactions were allowed to proceed for 60 min at room temperature and fluorescence measurements were recorded with a Tecan Infinity Spectrofluorimeter. The IC₅₀ values were determined from the percent inhibition versus concentration data using a sigmoidal non-linear regression analysis based on four parameters with Tecan Magellan software.

Example 32
HCV Replicon Assay

[00589] General procedure: Huh-7 cells containing HCV Conl subgenomic replicon (GS4.1 cells) were grown in Dulbecco’s Modified Eagle Medium (DMEM) supplemented with 10% fetal bovine serum (FBS), 2 mM L-glutamine, 110 mg/L sodium pyruvate, 1X non-essential amino acids, 100 U/mL penicillin- streptomycin, and 0.5 mg/mL G418 (Invitrogen). For dose-response testing, the cells were seeded in 96-well plates at 7.5 x 10³ cells/well in a volume of 50 µL, and incubated at 37 °C/5% CO₂. Three hours after plating, 50 µL often 2-fold serial dilutions of compounds (highest concentration, 75 µM) were added, and cell cultures were incubated at 37 °C/5% CO₂ in the presence of 0.5% DMSO. Alternatively, compounds were tested at a single concentration of 15 µM. In all cases, Huh-7 cells lacking the HCV replicon served as negative control. The cells were incubated in the presence of compounds for 72 hr after which they were monitored for expression of the NS4A protein by enzyme-linked immunosorbent assay (ELISA). For this, the plates were then fixed for 1 min with acetone/methanol (1:1, v/v), washed twice with phosphate-buffered saline (PBS), 0.1% Tween 20, blocked for 1 hr at room temperature with TNE buffer containing 10% FBS and then incubated for 2 hr at 37 °C with the anti-NS4A mouse monoclonal antibody A-236 (ViroGen) diluted in the same buffer. After washing three times with PBS, 0.1% Tween 20, the cells were incubated 1 hr at 37 °C with anti-mouse immunoglobulin G-peroxidase conjugate in TNE, 10% FBS. After washing as described above, the reaction was developed
with O-phenylenediamine (Zymed). The reaction was stopped after 30 min with 2 N H₂SO₄, and absorbance was read at 492 nm using Sunrise Tecan spectrophotometer. EC₅₀ values were determined from the % inhibition versus concentration data using a sigmoidal non-linear regression analysis based on four parameters with Tecan Magellan software. When screening at a single concentration, the results were expressed as % inhibition at 15 µM.

[00590] For cytotoxicity evaluation, GS4.1 cells were treated with compounds as described above and cellular viability was monitored using the Cell Titer 96 AQaurous One Solution Cell Proliferation Assay (Promega). CC₅₀ values were determined from the % cytotoxicity versus concentration data with Tecan Magellan software as described above.

[00591] The biological results are summarized in Table 5, wherein A represents a value smaller than 1 µM, and B represents a value between 1 µM to 10 µM, C represents a value between 10 µM to 75 µM and D represents a value greater than 75 µM.

**Resistance Profile**

[00594] Compounds were evaluated against three mutant proteases R155Q, A156S, and D168A, as summarized in Table 8, wherein A represents a value smaller than 1, and B represents a value between 1 to 10, and C represents a value greater than 10. The fold of change in inhibitory activity was determined by measuring the ratio of the inhibitory activity of a compound against a mutant enzyme over the inhibitory activity of the same compound against non-mutant enzyme. The inhibitory activity was determined using the procedure as described in Example 31.

**Generation of Recombinant JFH-I Virus Stocks**

[00595] The recombinant JFH-I HCV virus used in the HCV *in vitro* infection assay was generated by transfection of HPC cells with JFH-I RNA produced by *in vitro*

[00596] The cDNA for the JFH-I HCV clone was synthesized by DNA2.0 and contains a T7 promoter to drive the transcription of the JFH-I genomic RNA. This plasmid was amplified using the Hi-Speed Plasmid Midi kit (Qiagen) according to the manufacturer's instructions.

[00597] Thirty micrograms of purified DNA was digested overnight at 37 °C with 300 U XbaI. The digested DNA served as a template for the *in vitro* transcription of the JFH-I genomic RNA using the MEGAScript T7 kit (Ambion) as instructed by the manufacturer. The JFH-I RNA product was resuspended to 1 µg/µL in RNA storage solution (Ambion). The quality of the JFH-I RNA was verified by agarose gel electrophoresis (1.2% E-gel) prior to electroporation.

[00598] Complete growth media for Huh-7 and HPC cells (Huh-7 media) was prepared as follows: DMEM (containing glucose, L-glutamine and sodium pyruvate), 10% FBS, 100 IU/mL penicillin, 100 µg/mL streptomycin, 2 mM GlutaMAX, 1% MEM non-essential amino acids. Subconfluent HPC cells were treated with trypsin-EDTA, collected with Huh-7 media, and centrifuged at 1,500 rpm for 5 min at 4 °C in an Allegra 6R centrifuge (Beckman Coulter) in a 50 mL conical tube. The cells were then rinsed twice by resuspending the cells in 50 mL of PBS and centrifuging at 1,500 rpm for 5 min at 4 °C.

[00599] JFH-I RNA was electroporated into HPC cells using a Thermo Scientific Hybaid OptiBuffer kit (containing buffer A, solution B and compounds C and D). After washing, the HPC cells were resuspended in OptiBuffer buffer A at 1x10^7 cells/mL, and 400 µL (4x10^6 cells) was transferred to a 1.5 mL RNase-free microfuge tube and gently centrifuged at 2,000 rpm in a Microfuge 18 (Beckman Coulter) centrifuge at room temperature for 5 minutes. During this centrifugation step, the electroporation medium was prepared by mixing 2.5 mL of OptiBuffer solution B with 1 vial of OptiBuffer compound C (5.5 mg of ATP), 1 vial of OptiBuffer compound D (7.7 mg of glutathione) and 2.5 mL of autoclaved water. After aspirating the supernatant, the cell pellet was resuspended in 400 µL of electroporation medium. JFH-I RNA (8 µg) was added to the resuspended cells, whereupon they were transferred to a 0.4 cm cuvette and electroporated in a Bio-Rad
GenePulser XCell electroporation module with a single pulse at 960 µf, 270 V and maximum resistance. A mock transfection, without RNA, was electroporated as a negative control. Growth media (600 µL) was immediately added to the cuvette. Cells were then transferred into a 15 mL conical tube containing 3.4 mL of Huh-7 media. Approximately 1.2x10⁵ cells were seeded into each well of a Corning Costar 6-well plate and incubated at 37 °C with 5% CO₂.

[00600] When confluent, the transfected HPC cells were trypsinized and split 1:5 into new 6-well plates. At day 5 and 14 post transfection, conditioned media was collected from the cultures, cell debris was removed by centrifugation at 2,000 rpm for 10 min in a table-top centrifuge (Beckman Coulter Allegra 6R with GH3.8 rotor) and media was filtered through a 0.2 µm syringe-top filter. The transfected cells were also fixed for immunohistochemistry and lysed for immunoblotting analysis.

[00601] The recombinant JFH-I HCV virus was amplified in a manner described by (Zhong, et al, Proc. Nat. Acad. Sci. USA. 2005, 102:9294-9299). HPC cells were split to 10% confluency in 225 cm² flasks and infected with 1 mL of the transfected cell culture media (described above) at 5 hrs post seeding. At 5 days post infection (p.i.), the cultures were split 1:2 into new 225 cm² flasks. One half the initial culture media was carried over into the split cultures to facilitate virus amplification. At 10 day p.i., conditioned media was collected from the 225 cm² flasks, centrifuged at 2,000 rpm for 10 min in a table-top centrifuge and filtered through a MF75 sterilization filter (0.45 µm) bottle-top unit. Two milliliter aliquots of this virus stock were stored at -80 °C for future use.

HCV in vitro Infection Core ELISA Assay

[00602] The HCV in vitro infection core ELISA assay measures the ability of a test compound to inhibit replication of an infectious HCV (strain JFH-I; genotype 2a) in cell culture. Recently, an in vitro infection model identified by Wakita et al. (Nat. Med. 2005, 11:791-796) was found to replicate in retinoic acid-inducible gene I (RIG-I)-deficient or cluster of differentiation (CD)-8 1-positive Huh-7 hepatoma cell lines. We have developed this model for determining the efficacy of antiviral compounds against an infectious virus in vitro using HCV producing cells (HPC), a proprietary Huh-7-derived cell sublineage capable of propagating the JFH-I HCV virus. The readout of the assay is quantification of HCV core
protein by ELISA 5 days post infection with JFH-I virus and treatment with a test compound.

[00603] Ninety-six- well Corning Costar plates were seeded with HPC cells at a density of 3.0x10^3 cells per well in 50 µL of Huh-7 media. Compound stock solutions were made up freshly in Huh-7 media (DMEM (containing glucose, L-glutamine and sodium pyruvate), 10% FBS, 100 IU/mL penicillin, 100 µg/mL streptomycin, 2 mM GlutaMAX, 1% MEM non-essential amino acids) as 2X stock. Seven additional 3-fold drug dilutions were prepared from the 2X stocks in Huh-7 media. At least 4 hours after HPC cells were seeded, the media in the 96-well culture plates was aspirated and 50 µL of each drug dilution and 50 µL of JFH-1 HCV was added to each well.

[00604] At 16 hrs post treatment and infection, the virus inoculum was removed by aspiration. The cultures were treated at the same final concentrations of drug diluted to 1X in Huh-7 media to a final volume of 200 µL. Cells were incubated in the presence of drug for 4 additional days at 37°C/5% CO₂.

[00605] Media was removed from the plates by aspiration. Cells were fixed with 250 µL 1:1 acetone: methanol for 90 seconds, washed once in PBS and then three times with 1X KPL wash solution. The assay plates were then blocked with 150 µL/well 10% FBS-TNE (50 mM Tris-HCl (pH 7.5; Sigma), 100 mM NaCl, 1 mM EDTA with 10% FBS) for 1 hr at room temperature. Cells were washed three times with 1X KPL wash solution and incubated with 100 µL/well anti-hepatitis C core mAb (1 mg/mL stock diluted 1:500 in 10% FBS-TNE) for 2 hours at 37°C. Cells were washed three times with 1X KPL wash solution and incubated with 100 µL/well HRP-goat anti-mouse antibody (diluted 1:2,500 in 10% FBS-TNE) for 1 hr at 37°C.

[00606] OPD solution was prepared using 1 OPD tablet + 12 mL citrate/phosphate buffer (16 mM citric acid, 27 mM Na₂HPO₄) plus 5 µL 30% H₂O₂ per plate. Cells were washed three times with 1X KPL wash solution and developed with 100 µL/well OPD solution for 30 minutes in the dark at room temperature. The reaction was stopped with 100 µL/well of 2N H₂SO₄, and absorbance measured at A₃₉₀ nm in a Victor³ V 1420 multilabel counter (Perkin Elmer). The EC₅₀ values for each compound were calculated from dose response curves from the resulting best-fit equations determined by Microsoft Excel and XLfit 4.1 software. The negative control for inhibition of virus replication was untreated HPC cells infected with the JFH-I HCV virus strain. The negative ELISA control was
untreated, uninfected HPC cells. The positive ELISA control was untreated HPC cells infected the JFH-I HCV virus strain.

Example 38
MTS Cytotoxicity Assay

[00607] The cytotoxicity assay measures the viability of cells after treatment with a test compound for 5 days. The assay readout is the bioreduction of the yellow MTS tetrazolium compound to a purple formazan product. This conversion is mediated by NADPH or NADH and is directly proportional to the number of live cells in a culture.

[00608] Ninety-six-well Corning Costar plates were seeded with HPC cells at a density of 3x10^3 cells per well in 50 µL of Huh-7 media. Compound stock solutions were made up freshly in Huh-7 media as 2X stocks. Seven additional 3-fold drug dilutions were prepared from the 2X stocks in Huh-7 media for a total of 8 dilutions.

[00609] At least 4 hours after HPC cells were seeded, 50 µL of each drug dilution was added to the cultures. At 16 hrs post treatment, the existing media was removed by aspiration. Cultures were treated at the same final concentrations of drug diluted to IX in Huh-7 medium to a final volume of 100 µL. Cells were incubated for 4 additional days at 37°C/5% CO₂ in the presence of drug.

[00610] After 5 days of treatment, the CellTiter 96® Aqueous One Solution cell proliferation assay was performed by adding 20 µL of MTS solution to each well. The plates were then incubated at 37°C/5% CO₂ for 3 hours. Plates were read at A_{490} run in a Victor^3 V 1420 multilabel counter (Perkin Elmer) and CC_{50} concentrations were determined using Microsoft Excel and XLfit 4.1 software. The positive control for cell death: culture wells containing only Huh-7 medium. The negative control for cell death: culture wells containing untreated, uninfected HPC cells.

Example 39
HCV in vitro Infection Western Blotting Assay

[0061] This assay measures the ability of a test compound to inhibit replication of the JFH-I HCV strain in cell culture. The readout of the assay is the quantification of HCV NS3 or core protein by western blotting 5 days post infection with JFH-I virus and drug treatment.
Negative controls: untreated, uninfected HPC cells. Positive controls: untreated HPC cells infected the JFH-I HCV virus strain.

[00612] Twenty-four-well Corning Costar plates were seeded with HPC cells at a density of 1.5x10^4 cells per well in 0.8 mL of Huh-7 media (DMEM (containing glucose, L-glutamine and sodium pyruvate), 10% FBS, 100 IU/mL penicillin, 100 µg/mL streptomycin, 2 mM GlutaMAX, 1% MEM non-essential amino acids). Compound stock solutions were made up freshly in Huh-7 media as 10X stocks. Four additional 5-fold drug dilutions were prepared from the 10X stocks in Huh-7 media for a total of 5 dilutions.

[00613] At least 3 hrs after HPC cells were seeded, 100 µL of each drug dilution and 100 µL of JFH-I HCV was added to each well. At 16 hrs post treatment and infection, the virus inoculum was removed by aspiration. The cultures were treated at the same final concentrations of drug diluted to IX in Huh-7 media to a final volume of 1 mL. Cells were incubated in the presence of drug for 4 additional days at 37°C/5% CO₂.

[00614] Media was removed from the plates by aspiration and the cells washed with 1 mL of PBS. After removing the PBS, 100 µL/well of SDS sample buffer (50 mM Tris-HCl, pH7.5, 2% ultrapure SDS, 10% glycerol, 0.01% bromophenol blue, 0.1 M DTT) was added. The samples were collected into RNase-free microfuge tubes, incubated at 95 0°C for 5-10 minutes and centrifuged at maximum speed for 2 min in an Eppendorf 5415D centrifuge.

[00615] To prepare the Western Blot, fifteen microliters of each sample was loaded into each lane of a 4-20% Tris-glycine polyacrylamide gel in an XCell II Blot Module (Invitrogen); 6 µL of the SeeBluePlus2 prestained protein standard was also loaded into one lane. Each gel was run at 125 V for 1.5 hrs in Novex SDS (IX Tris/glycine/SDS) running buffer (Invitrogen). Each gel was transferred onto an iBlot nitrocellulose membrane using the iBlot apparatus (Invitrogen) according to the manufacturer's protocol. The membrane was rinsed in PBST (Sigma) and then blocked with 6 mL of blocking buffer (5% (w/v) nonfat milk in PBST solution) at room temperature for 1 hour with rocking. Each blot was incubated in 6 mL of blocking buffer containing HCV NS3 murine mAb (1:500; ViroGen Corp.) and anti-GAPDH murine IgG Ab (1:1,000,000; Calbiotech) or anti-core mAb (1:500; Affinity BioReagents) overnight at 4°C with rocking. After 3 ten minute washes in PBST at room temperature with rocking each blot was incubated with 6 mL of blocking buffer (5% (w/v) nonfat milk in PBST solution) containing HRP conjugated donkey anti-mouse Ab

224
(1:5,000) for 1 hour at room temperature with rocking. Each blot was washed as described above and then exposed to 5 mL of substrate from the SuperSignal West Dura substrate kit (Pierce) according to the manufacturer's protocol. The blots were then exposed using the Florochem 5,500 imager (Alpha Innotech).

Virus replication was quantified by determining the band densities of NS3 and core proteins using ImageQuant 5.2 software. Background (the density determined within the NS3 or core region with mock-transfected cells) was subtracted from NS3, core, and GAPDH band densities. Each corrected NS3 or core value was then normalized to the corresponding corrected GAPDH value for the same sample. The EC$_{50}$ value, which is the concentration of a test compound that reduced NS3 or core protein production by 50%, was determined for each compound using Microsoft Excel and XLfit 4.1 software. Each EC$_{50}$ value determination was performed in duplicate.
