Title: PROGESTERONE ANTAGONISTS SPIRO CONDENSED IN POSITION 17 WITH A DIFLUOROMETHYLENE-SUBSTITUTED PERHYDROFURANE GROUP

FIG. 1

Abstract: Described herein are compounds which exhibit progesterone antagonistic effects and methods of treating cancer using such compounds.
BACKGROUND

1. **Field of the Invention:** The present invention relates to suppressing the growth of cancer and other proliferative diseases by the administering of novel compounds that exhibit progesterone antagonism. The present invention also relates to processes of preparation and the use in therapy of such novel compounds.

2. **Description of the Relevant Art:** In the past, progesterone antagonists have been postulated to be of potential benefit in the treatment of breast cancer where the primary lesion contains both estrogen and progesterone receptors. In a recent study of an *in vivo* rat model of progesterone receptor positive breast cancer, it was shown that the administration of a new antiprogestin (Proellex, CDB-4124) resulted in a regression of tumor size as well as a decrease in the development of new tumors. FIG. 1 shows a series of selected progesterone antagonists that have been shown to be effective *in vitro* and *in vivo*. The prototype antagonist, Mifepristone (see FIG. 1), is characterized by the 19-nor-4,9-diene steroid nucleus, the 17α-propynyl-17β-hydroxy functionality, and the 11β-(4-dimethylamino)phenyl functional group which is believed to be responsible for its antagonistic activity. While Mifepristone is a potent progesterone antagonist, its long-term clinical use is limited due to its overt glucocorticoid receptor antagonism. Subsequent development undertaken by several groups has led to the discovery of several novel progesterone antagonists that are both more active than Mifepristone and more dissociated in relation to glucocorticoid antagonism. Some notable examples as outlined above in FIG. 1 and include Onapristone, ORG-33628, Proellex, and Lonaprisan (ZK-230211).

Of these examples, Lonaprisan is most notable in that it exhibits the highest antiprogestagenic activity and displays only marginal antiglucocorticoid effects. The high activity of Lonaprisan in comparison with the other analogs is somewhat surprising in that the normal effect on the introduction of a 17α-alkyl group in steroids is to increase its interaction with the androgen receptor, an effect not seen with this compound. However, the substitution of fluorine for hydrogen_
can often induce significant biochemical changes in a pharmaceutical molecule while causing only a
slight change in its shape.

While antiprogestin therapies have been effective in the treatment of some forms of cancer
(including breast cancers), there is still a need to develop more effective therapies.

The intermediate 17-spirodihydrofuran-3'(2'H)-one (2) may be synthesized following the procedure of Jiang et al. "New progesterone receptor antagonists: Phosphorus-containing 11β-aryl-substituted steroids." Bioorg Med Chem (2006) 14:6726-6732. Any suitable route of administration may be employed for providing a patient with an effective dosage of the progesterone antagonist compounds described herein. For example, oral, rectal, topical, parenteral, ocular, pulmonary, nasal, and the like may be employed. Dosage forms include tablets, troches, dispersions, suspensions, solutions, capsules, creams, ointments, aerosols, and the like. In certain embodiments, it may be advantageous that the compositions described herein be administered orally. The compounds are typically administered in admixture with suitable pharmaceutical diluents, excipients, or carriers (collectively referred to herein as "pharmacologically inert carriers") suitably selected with respect to the intended form of administration, that is, oral tablets, capsules, elixirs, syrups and the like, and consistent with conventional pharmaceutical practices.

The agonist and antagonist actions of the described progesterone antagonists may be tested using breast cancer cells. Established human breast cancer cell lines, such as MCF-7, T47D, MDMB231 and SKBR-3 and derivatives of these cell lines with/without PR expression, may be used to test the effect of the novel progesterone antagonists.

In one embodiment, a progesterone receptor reporter gene system may be used to evaluate the agonist and antagonist activities of the subject progesterone antagonists. Agonist and antagonist activities may further verified using a progesterone transactivation assay along with a proliferative effect assay of progesterone antagonists on these cells.

The in vitro biological activity of the progesterone antagonists may be compared to the activity of controls P4 (agonist) and RU486 (antagonist) using a cell based progesterone receptor element (PRE)-luciferase assay, as described in Giangrande et al. "The Opposing Transcriptional Activities of the Two Isoforms of the Human Progesterone Receptor Are Due to Differential Cofactor Binding." Mol Cell Biol (2000) 20:3102-3115, which is incorporated herein by reference.
The luciferase (luc) reporters 2XPRE-tk-luc contain two copies of the progesterone response element (PRE) upstream of a thymidine kinase (tk) promoter. This vector has been used in numerous studies to test the effect of various progesterone antagonists. Test progesterone antagonists may be evaluated for PR agonism and antagonism in this assay. Testing the PR agonist and antagonist activities with different concentrations of the progesterone antagonists may be used to determine their ability to block or enhance the PRE-luciferase activity and as a measure of their ability to bind and influence PR regulation using the T47D breast cancer cell line. This cell line expresses both human PR-A and PR-B forms of PR and is widely used for testing P4/PR effects. After determining the optimum concentration, the progesterone antagonists may be tested in different cell lines at the optimum concentration. Also their agonism and antagonism may be tested in PR-dependent transactivation assay.

In the luciferase assay, the reporter vector is first transfected into cells. After a limited amount of time, the cells are lysed and the substrate of luciferase, luciferin, is introduced into the cellular extract along with Mg and excess ATP. Under these conditions, luciferase enzyme expressed by the reporter vector will catalyze the oxidative carboxylation of luciferin. The luminescence from this chemical reaction can be read and quantified by a luminometer. The amount of light detected from the cell lysate correlates directly with the binding activity of the transcription factor. The Empty Control Vector may be used as a negative control for subtracting any background. The Empty Control Vector does not contain the transcription factor response element insert; it only contains the minimal TATA promoter and does not respond to any specific transactivation compound.

Transfections may be performed in 80% confluent 24h old cultures. For transient transfection, 200mg/well of PRE-luciferase DNA may be used. Lipofectamine 2000 may be used for transfection following the manufacturer's instructions. Unless otherwise specified, 5 ng/well of other optical reporters may be used for transfection normalization in the transient transfection studies. The cells may be assayed after 24h incubation at 37°C at 5% CO₂ with a specific concentration for each progesterone antagonist. The transfected cells may be lysed in 200 ml of ice-cold IX passive lysis buffer supplied by Promega and may then be shaken for 15 min on ice. The cell lysates may be centrifuged for 5 min at 1.3 x 10⁴ g at 4°C to remove cell debris. To determine Renilla luciferase activity, 20 nil of supernatant may be assayed by addition of 0.5 mg of coelenterazine in 100 ml of 0.5M sodium PBS at pH 7.0 (PBS), followed by photon counting in the
luminometer (model T 20/20; Turner Designed, Sunnyvale, CA) for 10 sec. Firefly luciferase activity may be determined as described for Renilla luciferase activity, except 100 ml of LARI substrate from Promega will be used. Protein concentrations in cell lysates may be determined by Bradford Assay (Bio-Rad Laboratories, Hercules, CA). Renilla luciferase activities may be normalized for protein content and for transfection efficiency using firefly luciferase activity and will be expressed as relative light units (RLU) per microgram protein per minute of counting.

To measure activation of PR, an ELISA-based PR transactivation assay may be performed as per manufacturer's guidelines (Panomics). Briefly, the nuclear lysates of cells or tumors may be generated as described by the manufacturer. Binding of ligand (agonist or antagonist) such as P4 or RU486 induces a conformational change in the receptor, allowing the receptor to bind to specific DNA sites; progesterone response elements. Activated PR from nuclear extracts may be allowed to bind to the PR consensus binding site (PR probe) on a biotinylated oligonucleotide. These oligonucleotides may then be immobilized on a streptavidin-coated 96-well plate. The PR bound to the oligonucleotide may be detected by an antibody directed against PR. An additional horseradish peroxidase-conjugated secondary antibody may provide colorimetric readout quantified by reading absorbance at 450 nm.

Using PRE-Luciferase assay and further validated with ELISA-based PR transactivation, it is possible to determine the agonist and antagonist activities of the progesterone antagonists. If mixed activity is seen, pure antagonist compounds may be tested to determine their efficacy in in vivo animal models. Further testing may be performed to determine the agonist and antagonist's activity on other reproductive tissues, especially for use in breast cancer treatment and prevention.

Nuclear Receptor Profiling

Determination of the agonist/antagonist nature of the test compounds was carried out using Invitrogen’s SelectScreen™ Cell-based nuclear receptor profiling service which uses the GeneBLAzer®-Beta-lactamase reporter technology. This assay uses a Beta-lactamase cDNA under transcriptional control of an Upstream Activator Sequence (UAS). The UAS is activated by the GAL4 transcription factor DNA binding domain (DBD), which is expressed as a fusion protein with the target receptor ligand binding domain (LBD). Upon ligand binding, the GAL4(DBD)-NR(LDB) binds to the UAS, which controls transcription of Beta-lactamase. Beta-lactamase cleaves a special engineered fluorescent substrate which results in a change in the measured fluorescence wavelength.

The generalized protocol used for the Progesterone Agonist screen is as follows:

The progesterone receptor-LBD-UAS-bla HEK 293T cells were thawed and resuspended in Assay Media (DMEM phenol red free, 2% CD-treated FBS, 0.1 nM NEAA, 1 mM Sodium Pyruvate, 100 U/mL/100µg/mL Pen/Strep) to a concentration of 468,750 cells/mL. 4 µL of a 10X serial dilution of control agonist R5020 (starting concentration, 100 nM) or test compounds are added to appropriate wells of a 384-well TC-Treated assay plate. 32 µL of cell suspension is added to each well. 4 µL of Assay Media is added to all wells to bring the final assay volume to 40 µL. The plate is incubated for 16-24 hours at 37 °C/5% CO2 in a humidified incubator. 8 µL of 1 µM Substrate
Loading Solution is added to each well and the plate is incubated for 2 hours at room temperature. The plate is then read on a fluorescence plate reader (Tecan Safire).

The generalized protocol used for the Progesterone Antagonist Screen, activated by control Agonist R5020 is as follows:

The progesterone receptor-LBD-UAS-bla HEK 293T cells are thawed and prepared as described above for the Agonist screen. 4 µL of a 1OX serial dilution of control antagonist RU-486 (starting concentration, 100 nM) or test compounds are added to appropriate wells of a TC-Treated assay plate. 32 µL of cell suspension is added to the wells which is then pre-incubated at 37 C/5% CO₂ in a humidified incubator with test compounds and control antagonist titration for 30 minutes. 4 µL of a 1OX control agonist (see above) at the predetermined EC80 concentration is added to wells containing the control antagonist or test compounds. The plate is incubated for 16-24 hours at 37 C/5% CO₂ in a humidified incubator. 8 µL of 1 µM Substrate Loading Solution is added to each well and the plate is incubated for 2 hours at room temperature. The plate is then read on a fluorescence plate reader (Tecan Safire).

The generalized protocol for the Glucocorticoid Antagonist Screen activated by control Agonist Dexamethasone was carried out as described for the Progesterone Antagonist Screen with the exception that glucocorticoid receptor-LBD-UAS-bla HEK 293T cells were used. The control antagonist used for the glucocorticoid assay was also RU-486.

The results of these tests for the indicated test compounds are shown in Table I
