Title: SYSTEM AND METHOD OF IDENTIFYING SOURCES ASSOCIATED WITH BIOLOGICAL RHYTHM DISORDERS

Abstract: An example system and method associated with identifying and treating a source of a heart rhythm disorder are disclosed. In accordance therewith, a spatial element associated with a region of the heart is selected. Progressive rotational activations or progressive focal activations are determined in relation to the selected spatial element over a period of time. The selecting and determining are repeated over multiple periods of time. A source parameter of rotation activations or focal activations is determined, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart. The determining of a source parameter is repeated for multiple regions of the heart. Thereafter, representation of the source parameter is displayed for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder.
SYSTEM AND METHOD OF IDENTIFYING SOURCES ASSOCIATED WITH BIOLOGICAL RHYTHM DISORDERS

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application claims the benefit of the priority of U.S. Provisional Application No. 62/330,734, filed May 2, 2016. For U.S. national stage purposes, this application is a continuation-in-part of U.S. Application No. 14/473,990, filed August 29, 2014, which claims the benefit of the priority of U.S. Provisional Application No. 61/973,626, filed April 1, 2014, and which is a continuation-in-part of U.S. Application No. 13/844,562, filed March 15, 2013, issued as U.S. Patent No. 9,332,915. Each of the foregoing applications is incorporated herein by reference in its entirety.

GOVERNMENT RIGHTS

[0003] This invention was made with government support under Grants R01 HL83359 and HL103800 awarded by the National Institutes of Health. The government has certain rights in the invention.

BACKGROUND

Field

[0004] The present application relates generally to biological rhythm disorders. More specifically, the present application is directed to a system and method of identifying a source (or sources) of a biological rhythm disorder, such as a heart rhythm disorder, by analyzing whether there exists continuous or interrupted activation associated with a source of a heart rhythm disorder (e.g., using a metric of progressive rotational or focal activation in relation to one or more spatial elements associated with the source of the heart rhythm disorder).
Brief Discussion of Related Art

Heart rhythm disorders are common and represent significant causes of morbidity and death throughout the world. Malfunction of the electrical system in the heart represents a proximate cause of heart rhythm disorders. Heart rhythm disorders exist in many forms, of which the most complex and difficult to treat are atrial fibrillation (AF), atrial tachycardias that interconvert and hence appear to fluctuate (IAT), multifocal atrial tachycardia (MAT), polymorphic ventricular tachycardia (VT) and ventricular fibrillation (VF). Other rhythm disorders are more simple and often easier to treat, but may also be clinically significant including atrial tachycardia (AT), supraventricular tachycardia (SVT), atrial flutter (AFL), premature atrial complexes/beats (SVE) and premature ventricular complexes/beats (PVC). While under normal conditions the sinus node keeps the heart in sinus rhythm, under certain conditions rapid activation of the normal sinus node can cause inappropriate sinus tachycardia or sinus node reentry, both of which also represent heart rhythm disorders.

Treatment of heart rhythm disorders ~ particularly complex rhythm disorders of AF, VF and VT ~ can be very difficult. Pharmacologic therapy for complex rhythm disorder is not optimal. Ablation has been used increasingly in connection with heart rhythm disorders by maneuvering a sensor/probe to the heart through the blood vessels, or directly at surgery, and delivering energy to a location of the heart to mitigate and in some cases to eliminate the heart rhythm disorder. However, in complex rhythm disorders ablation is often difficult and ineffectual because tools that identify and locate a cause (source) of the heart rhythm disorder are poor and hinder attempts to deliver energy to a correct region of the heart to eliminate the disorder.

Certain systems and methods are known for treating simple heart rhythm disorders. In a simple heart rhythm disorder (e.g., atrial tachycardia), the source of the disorder can be identified by tracing activation back to the earliest location, which can be ablated to mitigate and in some cases to eliminate the disorder. However, even in simple heart rhythm disorders, ablating the cause of a heart rhythm disorder is challenging and experienced practitioners often require hours to ablate simple rhythm disorders that show consistent beat-to-beat activation patterns, such as atrial tachycardia.

There are few, if any, known systems and methods that have been successful with respect to identifying the sources or causes for the direct treatment of complex rhythm disorders.
disorders such as AF, VF or polymorphic VT. In a complex rhythm disorder, an earliest location of activation onsets cannot be identified because activation onset patterns change from beat to beat and are often continuous without an earliest or a latest point.

[0009] Diagnosing and treating heart rhythm disorders generally involves the introduction of a catheter having a plurality of sensors/probes into the heart through blood vessels of a patient. The sensors detect electric activity of the heart at sensor locations in the heart. The electric activity is generally processed into electrogram signals that represent the activation of the heart at the sensor locations.

[0010] In a simple heart rhythm disorder, the signal at each sensor location is generally consistent from beat to beat, enabling identification of the earliest activation. However, in a complex rhythm disorder, the signal at each sensor location from beat to beat may transition between one, several, and multiple deflections of various shapes. For instance, when a signal for a sensor location in AF includes 5, 7, 11 or more deflections, it is difficult if not impossible to identify which deflections in the signal are local to the sensor location in the heart (i.e., local activation onset) versus a nearby sensor location in the heart (i.e., far-field activation onset) or simply noise from another part of the patient's heart, other anatomic structures or external electronic systems. The foregoing deflections make it difficult if not impossible to identify activation onset times of the beats in a signal at a sensor location.

[0011] Strategies in complex rhythm disorders have also considered regularity in signals at sensor locations as a surrogate for the source of the complex rhythm disorder, i.e., the source being more organized at certain sensor locations than at adjacent sensor locations. For example, U.S. 7,117,030 by Berenfeld et al. and U.S. 5,792,189 by Gray et al. exemplify approaches in which the source(s) for variable atrial fibrillation (AF) are considered highly regular and rapid. However, while these approaches have been validated in animal models, they may not be successful in finding and treating sources of atrial fibrillation in humans. As an example, Sanders et al. (Circulation 2005) found that locations of regularity, indicated by high spectral dominant frequency with a high regularity index, were rarely the locations where AF terminated by ablation in complex (persistent) AF. Other studies such as Sahadevan (Circulation 2004) identified locations of rapid regular activity in human AF that have not been shown to drive human AF. Animal models (Kalifa, Circulation 2006) and human studies (Nademane, J Am Coll 2004) suggest that complex fractionated atrial
electrograms (CFAE) may surround regular ‘drivers’ and may cause variable activation during AF. In clinical use, however, such CFAE sites reflect several competing and quite different phenomena, of which some are relevant to the causes of a heart rhythm disorder and others represent noise or artifact (Konings, Circulation 1997; Narayan, Heart Rhythm 2011; Calkins, Heart Rhythm 2012). As a result, CFAE are often unstable (e.g., varying in location over time or disappearing altogether), are found in large and widespread areas of heart tissue rather than being just in small discrete areas, and are usually identified inconsistently by a variety of relatively subjective criteria. Therefore, CFAE sites, in larger multicenter trials, have turned out to be poor targets for AF treatment with long term success (Oral, Circulation 2007; Oral J Am Coll Cardiol, 2009).

Accordingly, it is desirable to provide a system and method for detecting a source (or sources) of a heart rhythm disorder, particularly complex rhythm disorder including atrial fibrillation, interconverting or multifocal atrial tachycardias, polymorphic ventricular tachycardia or ventricular fibrillation, in the midst of complex colliding waves, competing sources and/or noise, which cause disorganization near the source, e.g., core of the disorder.

SUMMARY

The present application is applicable to identifying sources of various rhythm disorders and directly using this information to treat the rhythm disorders. It is also applicable to normal and disordered heart rhythms, as well as other biological rhythms and rhythm disorders, such as neurological seizures, esophageal spasms, bladder instability, irritable bowel syndrome, and other biological disorders for which biological signals can be recorded to permit determination, diagnosis, and/or treatment of the cause (or source) of the disorders. This application does not rely on activation mapping or examining regions of the biological organ (e.g., heart) that exhibit similar voltages (isopotential mapping) at sensor locations. It is thus particularly useful in complex rhythm disorders that exhibit complex activation patterns and complex varying signals, and is able to identify the source(s) of the complex rhythm disorders even if the sources are influenced and appear to be modified by such complex signals. It is especially useful in identifying the cause(s) of the disorders of the heart rhythm such that they can be treated with expediency.
[0014] The source indicates a region of the organ (e.g., heart) from where activation emanates to cause the complex rhythm disorder. Sources may include rotational circuits (rotors), from where waves, typically spiral waves, emanate to cause disorganized activation. Sources may also include focal impulse regions (e.g., focal sources), from where activation emanates centrifugally to cause disorganized activation.

[0015] The present application addresses several problems that have prevented the identification of sources for human complex rhythm disorders using methods routinely and historically applied to simple rhythm disorders. Using traditional analyses, electrogram shapes are often difficult to interpret in complex rhythm disorders. Sources precess (move) in limited spatial areas, such that traditional analyses from a fixed set of electrodes may not comprehend rotational activation (associated with a rotor) or centrifugal activation (associated with a focal source) when the source moves relative to the electrodes during and between consecutive beats. Disorganized activation from within or without the tissue can perturb and interrupt the spiral arms emanating from the rotor, which obscures rotation using traditional analyses (e.g., FIGS. 15-17 and 21). Electrical noise due to a variety of reasons, such as movement artifact from the movement of recording sensors or their physiological interface (e.g., body surface, cardiac tissue, etc.), poor electrode contact with the physiological interface, underlying electrical noise from the ambient environment, or near-field and far field signals, can make determination of activation particularly difficult in a rhythm with already underlying complexity.

[0016] Locating and identifying the source(s) of rhythm disorders enhances the ability to guide, select, and apply curative therapy, such as ablation. Determining the size and shape of a source(s) of a rhythm disorder enables therapy to be tailored to the particular source(s) to minimize damage to healthy tissue. In particular, the present invention provides a method to identify and locate electrical rotors, focal beats, and other heart rhythm disorders, and further to identify the size and shape of a region of tissue in which they migrate, which has never previously been determined. This property of migration is quite separate and distinct from a point source or a reentrant circuit that does not migrate, and defines a feature of complex rhythm disorders such as fibrillation of the atrium (AF) or the ventricle (VF), or other complex biological rhythm disorders. Once the shape is determined, treatment may be applied to at least a portion of the region and/or proximately to the region in certain cases to
ameliorate and potentially eliminate the disorder with minimal collateral damage, desirably using minimally invasive techniques as further described herein.

[0017] Precession of the source can obscure detection of a rotational circuit on fixed electrodes, since, for instance, the rotational activation around the core to the left (for instance at 06:00 clock face position during clockwise rotation) will be obscured if the core moves to the right, and similarly for other movements of the rotor core relative to fixed electrode over time (e.g., FIG. 15). The present invention detects such rotational activation. It also enables detection of rotational activation along a perimeter that is not clearly circular and may be ellipsoid or have another shape depending on the refractoriness and conduction properties of surrounding tissue. Such non-circular perimeters will also confuse traditional recording approaches, but can be detected by the present invention. Finally, this invention is able to detect rotational activation even if the sequence is interrupted along sectors (portions) of its perimeter (‘circumference’) by disorganized waves as described herein.

[0018] An important problem with diagnosis and treatment of complex heart rhythm disorders is that even when sources are identified, often multiple sources are present and difficult to identify concurrently. This can give the erroneous impression that fewer sources are present, or that sources "migrate" even though they are stable within a limited region ("precession locus"). Stable sources can be difficult to identify in this situation for many reasons. When multiple sources are present, a first source can be difficult to identify due to colliding and conflicting electrical waves from one or more additional sources. This may be because waves from a second or additional source may encroach upon the Organized domain’ of the first source, reducing its apparent size of 'control' (FIG. 3, upper right of panel). In this case, even though the first source continues to be present, it may be small or even below the detection resolution of the recording apparatus. Another issue with multiple sources is that electrical signals from the second or further sources may algebraically add to or cancel those from the first source. Nevertheless, multiple sources within a locus or spatial region over time can still be identified, either concurrently or in staggered periods of time alternating with the identification of other sources (FIG. 33). Additionally, if trying to observe one or multiple sources in real-time with continuous information, the data presented is so large that it becomes impossible for a human to visually track and interpret such information to identify all sources noted over time.
Additionally, disorganized activation can have numerous effects on the source. First, disorganized activation can arise if activation from the source undergoes disorganization away from its center or core (e.g., FIG. 16, left display). In this case, disorganized activation can surround the source but not perturb it, in which case, the central functionality of the source is largely unperturbed. If the source is associated with a complex rhythm disorder, such disorganization is often termed "fibrillatory conduction" from the rotor or focal source. The present invention provides the ability to quantify fibrillatory conduction and to define its functional effect, neither of which was previously characterized.

Disorganization (or fibrillatory conduction) can be due to functional properties such as abnormalities in repolarization, abnormalities in conduction, abnormalities in tissue capacitance, or abnormalities in impulse generation. This disorganization can also be due to the electrical impact of structural factors, such as heterogeneous cellular types (including fibrosis, scar, gene therapy or stem cell therapy), geometrical curvature of the organ (e.g., heart), or mechanical motion including stretch, piezoelectric effects and other manifestations of mechano-electrical feedback. This disorganization can also be due to abnormalities in nervous system function or innervation, such as the autonomic nervous system, resulting in abnormal spatially varying electrical properties in the tissue of the organ (e.g., heart).

Second, disorganized activation that surrounds the source but does not perturb it can also propagate towards the source from a second different spatially distinct region (e.g., FIG. 16, right display) or other cause of disorganization. The second source may be a second rotor or focal source of a complex rhythm (e.g. fibrillation). The second source may also be a simple rhythm within the body, such as the sinus nodal impulse (the body's internal pacemaker), a simple atrial tachycardia (e.g., typical atrial flutter), one or more spontaneous premature impulses (such as premature atrial complexes or PACs), one or more pacing impulses (e.g., from multiple leads of a cardiac pacemaker or biventricular or biatrial pacing device), a biological pacemaker from gene or other regenerative therapy, or other sources. The second source may also be outside the body, including external beam radiation, external pacing, external ablation energy sources, other electromagnetic radiation, or other sources. Disorganized activation at the interface between sources appears similar to "collision" or "fusion" as described in the literature in connection with simple rhythms or pacing, although its formation and its implications to treat human rhythm disorders in this invention are unique and distinct from that literature.
[0021] Third, disorganized activation can modify the source by altering its rate and/or regularity, while the source continues to operate (e.g., FIG. 17). Disorganized electrical waves can collide and may even combine with electrical components of source activation (e.g., similar to “fusion” in the literature on simple rhythms or pacing). This may alter the rate or regularity of the source, causing the source to appear irregular or complex (e.g., FIG. 18). A practical application of this invention is to tailor therapy to intentionally alter regularity of the source, convert the source to a simple regular rhythm that is more easily treated (e.g., atrial tachycardia), or to destabilize the source via complex oscillations (Frame and Simson, Circulation, 1988) such that the source self-terminates.

[0022] Fourth, disorganized activation can modify the source by altering its spatial location, while the source continues to operate (e.g., FIG. 19). This may cause the source to precess (move) in more constrained spatial areas, or potentially to meander in less constrained spatial areas. A practical application of the invention is to tailor therapy to intentionally modify the precession (limited spatial motion) of the source so that the source becomes fixed in a spatial area. This will essentially convert the source of a complex rhythm disorder into a simple rhythm disorder, such as an atrial tachycardia, that is relatively easy to treat. Treatment may thus be delivered using ablation, pacing strategies, gene or cellular therapy, or other forms of therapy. Another application of the invention is to intentionally alter the spatial location of the source to a region where it can no longer sustain, including inert regions of the organ (e.g., heart), to the edge of the organ, or even outside the organ.

[0023] Fifth, disorganized activation can invade the source to transiently terminate the source (e.g., FIG. 20). This can enable transient organization of the overall rhythm, or the source can be re-engaged. Re-engagement can take many forms. Re-engagement of the source (e.g., rotor) of a complex rhythm disorder, for instance, can take place in the opposite direction to its original activation sequence (e.g., clockwise whereas the source was formerly counterclockwise, or vice versa). This altered directionality may be more or less stable than the original direction. A practical application of the invention provides a potential therapy for the patient, by shifting activation of the source of a complex rhythm disorder (e.g., heart rhythm disorder) to a less stable form that is more easily treated and that may self-terminate.

[0024] Sixth, disorganized activation can invade the source and terminate for a prolonged period of time (e.g., FIG. 20). This can enable organization of the overall heart rhythm disorder into either normal (sinus) rhythm or a simple heart rhythm disorder that can
be easily treated (e.g., atrial fibrillation converting to atrial tachycardia; ventricular fibrillation converting to ventricular tachycardia). This can also enable change in the disorganized activation such that it may be sustained only transiently by disorganized activity without sources, or sustained by another source. This can be the basis for treating the source, whether it is for a simple rhythm disorder, such as a regular impulse generating region or circuit within an organized surrounding activation, or for a complex rhythm disorder, such as an organized impulse generating region or circuit within disorganized surrounding activation.

Seventh, there are certain effects on the heart by treating arrhythmias, including residual heart rhythm disorders or, if the arrhythmia is eliminated, the subsequent risk for arrhythmias. Treatment may comprise elimination of all sources, modulation or elimination of source(s) with a predominant impact on the overall rhythm (dominant sources), or modulation/elimination of non-dominant sources.

Treatment of all sources should eliminate the arrhythmia in the long-term, although the arrhythmia may continue transiently via disorganized activity ("fibrillatory conduction"). This transient fibrillatory conduction may be disorganized when measured by several metrics, and last from seconds to days. In the latter case, treatment may appear to result in "no apparent change" during the treatment procedure yet yield long-term treatment success (freedom from the arrhythmia). Cases have been observed when the arrhythmia (e.g., atrial fibrillation) terminates days or even weeks after treatment directed to sources by this approach and is then absent on follow-up for years.

Treatment of dominant source(s) may cause paradoxical disorganization of the arrhythmia, because regions are no longer organized by these source(s), yet may also yield long-term treatment success if remaining non-dominant sources are less capable of sustaining the arrhythmia alone.

Finally, treatment of non-dominant sources may cause organization of the arrhythmia using conventional analytical metrics. In this case, the remaining (dominant) source(s) may cause continued disease unless eliminated. As an example, this may include organized atrial tachycardias after ablation of AF that result from non-elimination of dominant sources. These considerations are critical for devising patient- and mechanism-tailored treatment strategies, i.e., precision medicine in the field of heart rhythm disorders.
This invention describes a system and method of determining whether rotational activation or focal activation is present during a heart rhythm disorder (e.g., complex heart rhythm disorder) within the context of electrical disturbances or noise mentioned above, and using this information to treat the human heart rhythm disorder in patients. In one embodiment, an index of progressive angular deviation (PAD) is determined, which indicates whether activation is rotational on one or more beats even if interruptions disrupt portions of the activation within any beat. Angles are assigned to progressively activating sites. If these sites demonstrate PAD, even if interrupted for a portion of the circumference due to physiology such as "fibrillatory conduction," rotational activity is assigned. The same approach can be used to identify a focal source as zero sum rotation in all directions (i.e. centrifugal activation) from a region of tissue. These regions (or sites) can be targeted for treatment (such as ablation) as described below.

In another embodiment, the invention uses the polar coordinate system, to measure the concept of progressive angular deviation around a pivot point (or rotor core). In this embodiment, a rotational activation trail will produce a perfectly spiral polar plot, while a centrifugal focal activation trail will produce a pattern representing simultaneous activation of electrodes on successively larger concentric circles around the focal origin. As before, deviations from these representations indicate disruptions due to disorganization from the complex or 'noisy' milieu (e.g., atrial fibrillation, ventricular fibrillation).

In yet another embodiment, this invention uses vectorial approaches to demonstrate rotational or centrifugal (focal) activation in simple or complex rhythm disorders. A vector is constructed that indicates the direction of activation between electrode sites in a pair and the speed of conduction between them, based upon differences in activation time and the relative distance. This is repeated for successive electrode pairs, then during and between successive heart beats (e.g., over time). Vectors that trace a circle are 'simple' reentry. If conduction slows for a portion, that arc of the circumference is shortened, making the vector loop more elliptical. This site of arc shortening (due to slow conduction) may be a prime target for therapy, such as ablation, drug therapy, pacing and so on.

The vectors may also trace an ellipse or another non-circular shape when the rotor core precesses. Vectorial analyses can also be computed using derived indexes such as principal components of activation (from mathematical principal component analysis), or
modifications based on identifying sites that can be activated within a time period consistent with known conduction velocities of normal and abnormal tissue.

[0033] In yet another embodiment, this invention uses counting schemes to indicate activation consistent with rotation or focal activation, to yield a 'rotational number' or 'focal number'. The simplest counting scheme for rotational activity includes incrementing a rotational counter when a site along a circular trajectory is activated. This can be modified for an elliptical perimeter, such as by 'combining' adjacent electrode sites so that the circular trajectory may be compressed in one axis. A rotational circuit is identified when the rotational counter exceeds a threshold in a specified time span in a defined spatial region.

[0034] Similarly, the simplest counting scheme for focal activity includes incrementing a centrifugal counter when activation affects a site along one or more radial trajectories. A focal source is identified when the focal counter exceeds a threshold in a specified time span in a defined spatial region.

[0035] Other schemes to detect rotational or focal sources include statistical methods such as Shannon entropy. Another embodiment includes only counting sites that activate with a similar electrogram (signal) shape along a trajectory (circular or centrifugal), for instance tracking the activation path or trail for 'signature' electrograms. Such signatures may be 'fractionated', monophasic or show specific frequency/spectral patterns. This may include sites with a narrow fundamental frequency, indicating a predominant rate in that region. The activation trail, indicative of the source for a heart rhythm disorder, may be a modified rotational (circular or elliptical) trial, or modified focal (radial or anisotropic radial) trail.

[0036] A series of trigonometric indexes can also be constructed to indicate rotational activation, such as by using the sine function which rises progressively from 0 to 1, then to -1 then to 0 in a plausible time-period for sites within a defined spatial region. Analogous logic applies to the construction of other trigonometric indexes that use the cosine or other trigonometric, inverse trigonometric, hyperbolic or inverse hyperbolic functions.

[0037] In still another embodiment, correlation analyses are used. In this embodiment, a spatial pattern of activations indicative of a heart rhythm disorder (an activation trail) can be correlated to the pattern on successive cycles to determine if the pattern repeats, even if the partem is interrupted by invading wavefronts or other
disorganization in a complex rhythm disorder. This invention can also be used to find centrifugal activation (a 'focal beat') despite interruptions.

[0038] One concept embodied in the invention is that driver regions for an arrhythmia may be maintained by additional primary sources. For instance, a rotor or focal source may activate dependently with secondary sources in a "mother-daughter" fashion. Mother-daughter rotors should be synchronized in some fashion, potentially with a time-delay (or phase shift), and thus may be detected by correlation or phase methods to identify primary driver regions from secondary regions.

[0039] In all embodiments, rotational activations or focal activations can be identified in the midst of complex surrounding disorganization. In cases of simple rotational circuits (e.g., FIG. 21, "simple" display), the rotational, angular, vectorial or other sequence of representation are uninterrupted. However, this sequence becomes progressively less clear with greater and greater surrounding disorganization, interruption or "fibrillatory conduction" (e.g., FIG. 21, "precession, "discontinuous", and "interrupted" displays). Similarly, focal sources are identified in the midst of a complex arrhythmia with surrounding disorganization.

[0040] In each case of interrupted/discontinuous sources, how rotational or centrifugal activation trails are interrupted, spatially and temporally, can yield important information. If the interruptions are temporally reproducible, for instance at a specific rate, they may represent interruption from a secondary source. Such a source may be asynchronous to the source being measured. The spatial direction from which the interruption is detected, for instance, consistently from a septal or right atrial location, may indicate the relative direction from which additional source(s) occur. Such information can be used computationally to help detect potential sources from those directions, which can be targeted for improved treatment.

[0041] In the various embodiments, analyses of rotational or centrifugal (focal) activation are performed within a defined spatial region that encompasses an area of precession (limited meander or 'wobble') of a rotor or focal source of a rhythm disorder. In simple rhythm disorders, this precession area is very small (effectively zero, but actually non-zero due to slight stochastic changes in functional property of tissue over time). In complex rhythm disorders such as atrial fibrillation, the precession area of a source is on average 2-3 cm² (< 10 cm²) of tissue surface.
The area of precession, within which the source of the rhythm disorder is analyzed, can be varied. In particular, detection can be tailored to the diagnostic or treatment strategy employed. For instance, if an ablation catheter has a lesion diameter of 7 mm, the precession area of analysis need not be smaller than that.

Detection of areas of precession can be tailored to each patient. This can be based upon factors such as proximity of the analysis zone to regions of structural abnormality (scar or fibrosis), or abnormal regions of function (repolarization or conduction). In more sophisticated analyses, the precession area can be increased in patients with enlarged atria from a disease state called remodeling. The area may also increase in patients whose arrhythmia continues despite extensive prior ablation.

Factors that influence the precession area can be incorporated into a database, and accessed in software using a lookup table. This database may include, but is not limited to, patient gender, age, number of years with the rhythm disturbance, source locations, type of disorder (such as paroxysmal or persistent AF) and so on.

This invention enables a determination of a source (or sources) of the heart rhythm disorder for treatment. An advantage of the present method and system is that they can be carried out rapidly while a sensing device ~ such as a catheter having sensors thereon ~ is used in or near the patient and is followed by treatment of cardiac tissue to ameliorate the disorder and in many cases to cure the disorder. Treatment may thus occur immediately, since the invention will provide the location(s) of the source of the heart rhythm disorder.

In accordance with an embodiment, a method of identifying and treating a biological rhythm disorder is disclosed. In accordance with the method, cardiac signals are processed to measure rotating cardiac activity in a region of tissue and cardiac activity that is not part of the measured rotating cardiac activity in the region of tissue. One or more regions of tissue are determined wherein rotating cardiac activity predominates over non-rotating cardiac activity to define a rotational source (e.g., rotor). Alternatively, one or more regions of tissue are determined wherein centrifugal cardiac activity predominates over non-centrifugal cardiac activity to define a focal source. Such regions may interact and interconvert. At least one portion of the tissue is identified proximate to the source to enable selective modification of the at least one portion in order to treat the heart rhythm disorder.
In accordance with another embodiment, a system to identify and treat a biological rhythm is disclosed. The system includes a processor and a memory storing instructions that, when executed by the processor, cause the processor to perform the following operations. The operations include processing cardiac signals via a computing device to measure rotating cardiac activity in a region of tissue. The operations further include measuring cardiac activity that is not part of the measured rotating or centrifugal cardiac activity in said region of tissue. The operations also include determining one or more regions of tissue wherein rotating cardiac activity predominates over non-rotating cardiac activity to define a source. Furthermore, the operations include identifying at least one portion of the tissue proximate to the source to enable selective modification of the at least one portion in order to treat the heart rhythm disorder.

In accordance with further embodiment, a storage medium storing instructions that, when executed by the processor, cause the processor to perform the following operations is disclosed. The operations include processing cardiac signals via a computing device to measure rotating cardiac activity in a region of tissue. The operations further include measuring cardiac activity that is not part of the measured rotating cardiac activity in said region of tissue. The operations also include determining one or more regions of tissue wherein rotating cardiac activity predominates over non-rotating cardiac activity to define a source and. Furthermore, the operations include identifying at least one portion of the tissue proximate to the source to enable selective modification of the at least one portion in order to treat the heart rhythm disorder.

In accordance with an embodiment, a method of determining consistency of activation (repeatability even in noisy signals) associated with a heart rhythm disorder is disclosed. In accordance with the method, a spatial element associated with a region of the heart is selected. Progressive rotational activations or progressive focal (centrifugal) activations are determined in relation to the selected spatial element. A plurality of indexes of the progressive rotational activations or the progressive focal activations is formed. One or more indexes are selected from the plurality of indexes that indicate consistency of the progressive rotational activations or the progressive focal (centrifugal) activations in relation to a portion of the region of the heart.

In accordance with another embodiment, a system to determine consistency of activation associated with a heart rhythm disorder is disclosed. The system includes a
processor and a memory storing instructions that, when executed by the processor, cause the processor to perform the following operations. The operations include selecting a spatial element associated with a region of the heart. The operations also include determining progressive rotational activations or progressive focal activations in relation to the selected spatial element. The operations further include forming a plurality of indexes of the progressive rotational activations or the progressive focal activations. Furthermore, the operations include selecting one or more indexes from the plurality of indexes that indicate consistency of the progressive rotational activations or the progressive focal activations in relation to a portion of the region of the heart.

[0051] In accordance with further embodiment, a storage medium storing instructions that, when executed by the processor, cause the processor to perform operations for determining consistency of activation associated with a heart rhythm disorder is disclosed. The operations include selecting a spatial element associated with a region of the heart. The operations also include determining progressive rotational activations or progressive focal activations in relation to the selected spatial element. The operations further include forming a plurality of indexes of the progressive rotational activations or the progressive focal activations. Furthermore, the operations include selecting one or more indexes from the plurality of indexes that indicate consistency of the progressive rotational activations or the progressive focal activations in relation to a portion of the region of the heart.

[0052] In accordance with an embodiment, an aggregate, summated, or average representation is provided to combine the identified regions where each source has been identified over time. This preferred embodiment of the representation is dynamically updated as more data is processed to identify regions where a source is present. Such a representation may include an image, a series of images, or a composite movie of the images in continuous or 'time-lapse' form. Each image conveys the three-dimensional structure of the mapped biological (heart) chamber together with source identification. Source identification may take the form of relative numerical percentages, ratios, color coding, three dimensional 'bar charts' or 'topological' maps, or other relative information to provide a user with qualitative and/or quantitative information regarding how frequently a source is identified in a particular region of the representation of the heart.

[0053] These aggregate, summated or average quantities may be simple summations, or may be weighted based on criteria such as the number of rotations of the source, the size of
the chamber influenced ('controlled') by the source, wavefront propagation from/to the
source, stability of wavefronts associated with the source, centrifugal patterns such as those
that may be associated with focal sources, or other factors. Information may also be provided
to convey how likely a region is to harbor a source. In this way, less 'strong' or less
'convincing' sources, such as those that are continuously interrupted in their course by
interaction with additional sources, may be represented differently from definitive source
regions. Other embodiments of the aggregate, summated, or average representation may
include video images with source regions and/or characteristics associated with sources,
numerical displays, icons, or other representative symbols to identify the spatial region
displayed either on an isolated display, a three dimensional abstract representation, a three
dimensional representation of the cardiac tissue, polar representations, or other geometric or
cartographic representations that correlate to the cardiac tissue. These images are thus n-
dimensional, providing three (3) structural dimensions, and at least one (1) dimension for the
source parameter at each structural location.

[0054] In accordance with another embodiment, a method associated with identifying
and treating a source of a heart rhythm disorder is disclosed. In accordance with the method,
a spatial element associated with a region of the heart is selected. Progressive rotational
activations or progressive focal activations are determined in relation to the selected spatial
element over a period of time. The selecting and determining are repeated over multiple
periods of time. A source parameter of rotational activations or focal activations is
determined, wherein the source parameter indicates consistency of successive rotational
activations or focal activations in relation to a portion of the region of the heart. The
determining of a source parameter is repeated for multiple regions of the heart. A
representation of the source parameter is displayed for each of the multiple regions of the
heart to identify a shape representing the source of the heart rhythm disorder.

[0055] In accordance with a further embodiment, a system associated with identifying
and treating a source of a heart rhythm disorder is disclosed. The system includes a processor
and a memory storing instructions that, when executed by the processor, cause the processor
to perform the following operations. The operations include selecting a spatial element
associated with a region of the heart, and determining progressive rotational activations or
progressive focal activations in relation to the selected spatial element over a period of time.
The operations also include repeating the selecting and determining over multiple periods of
time, and determining a source parameter of rotational activations or focal activations, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart. The operations further include repeating the determining of a source parameter for multiple regions of the heart. Furthermore, the operations include displaying a representation of the source parameter for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder.

[0056] In accordance with yet another embodiment, there is disclosed a storage medium storing instructions that, when executed by the processor, cause the processor to perform operations associated with identifying and treating a source of a heart rhythm disorder. The operations include selecting a spatial element associated with a region of the heart, and determining progressive rotational activations or progressive focal activations in relation to the selected spatial element over a period of time. The operations also include repeating the selecting and determining over multiple periods of time, and determining a source parameter of rotation activations or focal activations, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart. The operations further include repeating the determining of a source parameter for multiple regions of the heart. Furthermore, the operations include displaying a representation of the source parameter for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder.

[0057] In some embodiments or aspects, the source parameter can be associated with a frequency of successive rotational activations in the region of the heart. The source parameter can be associated with a frequency of progressive angular displacement in the region of the heart. Moreover, the source parameter can be a regularity with which the rotational activations or focal activations are present. In this regard, the regularity may be one of periodicity, repetitiveness, and/or frequency of occurrence of rotational or focal activations.

[0058] In some embodiments or aspects, the representation can use an arithmetic mean of the source parameter of the region over time. The representation can also use a geometric or other mean of the source parameter of the region over time. Moreover, the representation can use a weighted average of the source parameter of the region over time.
In accordance with still another embodiment, a method of identifying and treating a source of a heart rhythm disorder is disclosed. In accordance with the method, a spatial element associated with a region of the heart is selected. Progressive rotational activations or progressive focal activations are determined in relation to the selected spatial element over a period of time. The selecting and determining are repeated over multiple periods of time. A source parameter of rotational activations or focal activations is determined, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart. The determining of a source parameter is repeated for multiple regions of the heart. A representation of the source parameter is displayed for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder. Thereafter, a region of the heart associated with the shape is selectively modified in order to terminate or alter the heart rhythm disorder.

These and other purposes, goals and advantages of the present application will become apparent from the following detailed description of example embodiments read in connection with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Some embodiments are illustrated by way of example and not limitation in the figures of the accompanying drawings in which:

FIG. 1 illustrates an example system to identify a source (or sources) of a heart rhythm disorder;

FIGS. 2-5 illustrate an example embodiment for the formation of progressive angular deviations (PADs) in relation to a spatial element;

FIGS. 6-7 illustrate a first correlation of PADs in an analysis time interval;

FIGS. 8-10 illustrate a correlation of PADs using a first time window in an analysis time interval;

FIGS. 11-12 illustrate a second correlation of PADs using a second time window in an analysis time interval;
FIG. 13 illustrates a method of determining and correlating progressive angular deviations (PADs) in connection to spatial elements;

FIG. 14 illustrates a general computing system to perform one or more methods or functionalities disclosed herein;

FIG. 15 illustrates example precession of a rotating source (locus) of a complex heart rhythm disorder, and how this will prevent detection of rotation at fixed electrodes using classical methods;

FIG. 16 indicates disorganization that does not disturb the source. (1) Fibrillatory conduction, i.e., disorganization away from the center of the source. (2) Peripheral disorganized activation towards the center of the source that does not perturb the central elements of the source;

FIG. 17 illustrates the concept of interruption of peripheral portions of a source, for instance, interruption of the rotating spiral arms around a rotor source, by disordered activation. This will prevent detection of sequential rotational activation at fixed electrodes using classical methods of activation mapping, isopotential mapping, or isochronal analysis;

FIG. 18 indicates disorganization that perturbs the rate/regularity of a source. As illustrated, the disorganization constrains irregularity, making it more regular. The opposite may also occur;

FIG. 19 indicates disorganization that perturbs the spatial localization of a source. (1) disorganization constrains spatial precession, making the source locus smaller and the rhythm more regular. (2) disorganization exacerbates source precession, the rotor precesses to another region of the heart, where it may self-terminate or be easier to treat;

FIG. 20 indicates disorganization that perturbs the source to the point of terminating the source of the disorder;

FIG. 21 illustrates mathematical approaches to identify sources through perturbations, and thus to quantify perturbations. (1) Unperturbed source, indicated by linear progressive angular deviation (PAD) correlations of X₁... Xₙ for repeated cycles of activation. (2) Precession, with deviations of PADs from the ideal PAD correlations. (3)
Discontinuous, where external disorganized activity fuses with peripheral portions of the source. (4) Interrupted, where external disorganized activity eliminates portions of rotation around the source;

[0076] FIG. 22 is an example flowchart associated with characterizing progressive angular deviations (PADs) of a rotational source in relation to a potential site;

[0077] FIG. 23 is an example flowchart associated with characterizing progressive angular deviations (PADs) of a focal source in relation to a potential site;

[0078] FIG. 24 indicates progressive angular deviations near-ideally correlated (lines of correlation) indicating uninterrupted rotors with minimal precession. Similar results could be obtained using another metric of progressive rotation;

[0079] FIG. 25 indicates correlated progressive angular deviations that show rotational activation although the rotor periphery (spiral arms) are interrupted and the rotor core precesses. Similar results could be obtained using another metric of progressive rotation;

[0080] FIG. 26 indicates two concurrent rotors for which correlations of the progressive angular deviations show both rotors (of opposite chirality) despite each interfering with the other. Similar results could be obtained using another metric of progressive rotation;

[0081] FIG. 27 indicates an example flowchart of the logic for polar analysis of rotations (PAR) for rotational activation trails during a heart rhythm disorder;

[0082] FIG. 28 indicates an example flowchart of the logic for polar analysis of rotations (PAR) for centrifugal activation trails during a heart rhythm disorder;

[0083] FIG. 29 illustrates a rotor in the left atrium that drives atrial fibrillation, with disorganized activity in the right atrium. The rotor is counterclockwise;

[0084] FIG. 30 indicates polar analyses at the core of the rotor in FIG. 29, which indicates polar metrics of rotational activity;

[0085] FIG. 31 indicates polar analyses just outside the core of the rotor in FIG. 29, which shows polar metrics indicating partial rotational activity;
FIG. 32 indicates polar analyses of rotation (PAR) outside the core of the rotor in FIG. 29, which shows polar metrics indicating passive non-rotational activation; and

FIGs. 33A-33D show averaging/aggregating of concurrent sources, illustrated by isochronal representations of rotational activation sources at two different regions ("site 1" and "site 2"), surrounded by disorganized activation, over four different time segments in the same patient.

DETAILED DESCRIPTION

A system and method for identifying one or more sources of a biological rhythm disorder (e.g., heart rhythm disorders) are disclosed herein. In the following description, for the purposes of explanation, numerous specific details are set forth in order to provide a thorough understanding of example embodiments. It will be evident, however, to one skilled in the art, that an example embodiment may be practiced without all of the disclosed specific details.

FIG. 1 illustrates an example system 100 to identify a source (or sources) of a biological rhythm disorder (e.g., heart rhythm disorder) in a human patient. Specifically, the example system 100 is configured to access cardiac information (signals) collected/detected from the patient's heart in connection with the heart rhythm disorder. The system 100 is further configured to process the signals in order to determine at least one spatial area including one or more spatial elements about which there is progressive angular deviation (PAD) of activation (e.g., activation onset times) associated with other spatial elements for a number activation cycles. Progressive angular deviation will show rotation that proceeds around the spatial area even if the sequence is interrupted along sectors (portions) of its perimeter ('circumference'). This approach also enables detection of rotational activation in a perimeter that is not clearly circular and may be ellipsoid or have another shape depending on the refractoriness and conduction properties of surrounding tissue. A region of the heart associated with a spatial area can be selected for treatment (e.g., ablation) to ameliorate and in many cases to cure the heart rhythm disorder.

As shown in FIG. 1, the heart includes a right atrium 122, left atrium 124, right ventricle 126 and left ventricle 128. The example system 100 includes a catheter 102, signal processing device 114, computing device 116 and analysis database 118.
The catheter 102 is configured to detect cardiac activation information in the heart and to transmit the detected cardiac activation information to the signal processing device 114, via a wireless connection, wired connection, or a combination of both wired and wireless connections. The catheter includes a plurality of probes/sensors 104-112, which can be inserted into the heart through the patient's blood vessels. Sensors may detect unipolar and/or bipolar signals from the patient's heart 120.

In some embodiments or aspects, one or more of the sensors 104-112 may not be inserted into the patient's heart. For example, some sensors may detect cardiac activation via the patient's surface (e.g., electrocardiogram - ECG) or remotely without contact with the patient (e.g., magnetocardiogram). As another example, some sensors may also derive cardiac activation information from cardiac motion of non-electrical sensing device (e.g., echocardiogram). In various embodiments or aspects, these sensors can be used separately or in different combinations, and further, these separate or different combinations can also be used in combination with sensors inserted into the patient's heart 120.

The sensors 104-112, which are positioned at sensor locations in respect to the heart 120 under consideration, can detect cardiac activation information at the sensor locations and can further deliver energy to ablate the heart at the sensor locations. It is noted that the sensors 104-112 can also detect cardiac activation information from overlapping regions of the heart (e.g., right atrium 122 and left atrium 124).

The catheter 102 can transmit the sensed cardiac activation information of the sensors 104-112 to the signal processing device 114. The signal processing device 114 is configured to process (e.g., clarify and amplify) the cardiac activation information detected by the sensors 104-112 at the sensor locations into electrogram signals and to provide the processed signals to the computing device 116 for analysis in accordance with methods disclosed herein. In processing the cardiac activation information from the sensors 104-112, the signal processing device 114 can subtract cardiac activation information from overlapping regions of the heart 120 to provide processed signals to the computing device 116 for analysis. While in some embodiments or aspects, the signal processing device 114 is configured to provide unipolar signals, in other embodiments, the signal processing device 114 can provide bipolar signals.
The computing device 116 is configured to receive or access the detected and processed signals from the signal processing device 114 and further configured to analyze the signals in accordance with methods disclosed herein to determine at least one spatial area including one or more spatial elements about which there is progressive angular deviation (PAD) of activation (e.g., activation onset times) associated with other spatial elements for a number activation cycles.

The computing device 116 is further configured to generate and display an activation propagation map (APM) video 150, which combines and displays spatially the activation information from a plurality of signals, which may take many forms including monophasic action potential (MAP) signal representations. The APM video 150 includes a sequence of APM frames that are associated with a series of time increments over an analysis time interval (e.g., 4000 msec or another analysis time interval). The arrow 152 indicates rotational movement of the activation information. The spatial elements in the MAP representation are associated with sensors 104 in an array of sensors. The signal (in this case MAP representation) includes voltage (or charge) versus time and other indexes. The signal representation may also include activation onset time information associated with the electrical activity sensed by a sensor 104 of the array of sensors. The MAP representation can be mapped as curves on time and voltage axes, as well as several other representations including polar plots and three-dimensional plots.

As used herein, activation onset time is a time point at which activation commences in a cell or tissue, as opposed to other time points during activation. Activation is a process whereby a cell commences its operation from a quiescent (diastolic) state to an active (electrical) state.

The computing device 116 receives, accesses, or generates the representations of the APM video 150. As an example of the generation of an APM video 150 and representations in the form of monophasic action potentials (MAPs) is described in U.S. Patent No. 8,165,666, which is incorporated herein by reference in its entirety. In particular, FIG. 11 of the '666 patent illustrates an APM video 150 of MAPs.

Other methods and systems that provide such representations can be used. The APM video 150 may be generated by any other systems and methods that can reconstruct
cardiac or biological information over time to generate a dynamic representation of activation information.

[00100] The analysis database 118 is configured to support or aid in the analysis of the signals by the computing device 116. In some embodiments, the analysis database 118 can store the APM video 150, as will be described in greater detail herein. The analysis database 118 can also provide storage of intermediate data (e.g. PAD pairs of spatial elements) associated with the determining one or more areas associated with a heart rhythm disorder.

[00101] FIG. 2 illustrates an example frame representation 200 of the APM video 150 (e.g. a monophasic action potential (MAP) as described in U.S. Patent No. 8,165,666) received, accessed, or generated by the computing device 116. The APM video 150 identifies activation information for a selected analysis time interval or period of time (e.g., 4000 msec) associated with a heart rhythm disorder. For illustrative purposes, the frame representation 200 illustrates activation information occurring at a first time point (e.g., 10 msec) of the analysis time interval.

[00102] A spatial element 202 associated with a sensor (e.g., indicated in red) is selected for processing in the APM video 150. It should be noted that one or more of a plurality of spatial elements (e.g., spatial elements 120 from FIG. 1) can be processed sequentially or in parallel in accordance with the methodology described herein in connection with spatial element 202.

[00103] A circle 204 (e.g., indicated in green) having a radius (e.g., two (2) sensor distance) extending from the selected spatial element 202 is determined. The radius is given as an example, and a larger or a smaller radius can be selected. Thereafter, a set including a plurality of sensors 104 on or within the circle 204 is then determined for processing in connection with spatial element 202. It should be noted that a differently dimensioned and/or sized shape can be used (e.g., square, diamond, etc.) to determine the set.

[00104] The first time point (10 msec) indicates a first activation onset time of any sensor in the determined set of sensors during the analysis time interval (e.g., 4000 msec). For example, the activation onset time at 10 msec is associated with a sensor 206. The black line 201 indicates 0…2pi about the circle 204 in a counterclockwise direction. An angle 208 is determined from the selected spatial element 202 to the associated sensor 206. Thereafter, a pair which includes the angle and the activation time is generated (e.g., Pair 1 = (pi/2, 10)
for the first activation onset time. It should be noted that one or more additional pairs can be generated for any another sensors in the set that have associated activation onset time at 10 msec.

[00105] FIG. 3 illustrates an example frame representation 210 of the APM video 150 received, accessed, or generated by the computing device 116. For illustrative purposes, the frame representation 210 illustrates activation information occurring at a second time point (e.g., 36 msec) of the analysis time interval (e.g., 4000 msec).

[00106] The second time point (36 msec) indicates a second activation onset time of any sensor in the determined set of sensors during the analysis time interval (e.g., 4000 msec). For example, the activation onset time at 36 msec is associated with a sensor 212. An angle 214 is determined from the selected spatial element 202 to the associated sensor 212. Thereafter, a pair which includes the angle and the activation time is generated (e.g., Pair 2 = (pi/2, 36) for the second activation onset time. It should be noted that one or more additional pairs can be generated for any another sensors in the set that have associated activation onset times at 36 msec.

[00107] FIG. 4 illustrates an example frame representation 216 of the APM video 150 received, accessed, or generated by the computing device 116. For illustrative purposes, the frame representation 216 illustrates activation information occurring at a third time point (e.g., 62 msec) of the analysis time interval (e.g., 4000 msec).

[00108] The third time point (62 msec) indicates a third activation onset time of any sensor in the determined set of sensors during the analysis time interval (e.g., 4000 msec). For example, the activation onset time at 62 msec is associated with a sensor 218. An angle 220 is determined from the selected spatial element 202 to the associated sensor 218. Thereafter, a pair which includes the angle and the activation time is generated (e.g., Pair 3 = (pi, 62) for the third activation onset time. It should be noted that one or more additional pairs can be generated for any another sensors in the set that have associated activation onset time at 62 msec.

[00109] FIG. 5 illustrates an example frame representation 222 of the APM video 150 received, accessed, or generated by the computing device 116. For illustrative purposes, the frame representation 222 illustrates activation information occurring at a fourth time point (e.g., 77 msec) of the analysis time interval (e.g., 4000 msec).
The fourth time point (77 msec) indicates a third activation onset time of any sensor in the determined set of sensors during the analysis time interval (e.g., 4000 msec). For example, the activation onset time at 77 msec is associated with a sensor 224. An angle 224 is determined from the selected spatial element 202 to the associated sensor 224. Thereafter, a pair which includes the angle and the activation time is generated (e.g., Pair 4 = (5pi/4, 77) for the fourth activation onset time. It should be noted that one or more additional pairs can be generated for any another sensors in the set that have associated activation onset time at 77msec.

For illustrative purposes, FIGS. 2-5 detail four (4) example frame representations of activation onset times associated with sensors in the determined set of sensors occurring during the analysis time interval (e.g., 4000 msec). However, it should be noted that there could be significantly more activation onset times associated with sensors in the determined set during the analysis time interval (e.g., 4000 msec).

FIG. 6 illustrates a graphical representation 600 of the generated pairs 605. The graphical representation 600 illustrates the generated pairs 605 plotted on a time-angle graph, i.e., angle 602, time 604. As an example, pair 1 (pi/2, 10) of frame representation 200 is plotted as pair 606 and pair 4 (5pi/4, 77) of frame representation 222 is plotted as pair 612. It should be noted that the graphical representation 600 illustrates a plurality of generated pairs 605, such as pairs 606-620, which are shown for illustrative purposes.

FIG. 7 illustrates a graphical representation 700 showing the calculation of lines that best fit pairs of the plurality of pairs 605 in a window 702 (e.g., first window) anchored at a first pair 606. A size of the first window 702 is defined to be a predetermined percentage (e.g., 75%) of a cycle length that is determined to be associated with the heart rhythm disorder. It should be noted that the cycle length associated with the heart rhythm disorder can be a median cycle length, an average length, or another threshold cycle length that is determined in connection with the heart rhythm disorder.

Determination of the size of the first window 702 can vary with the specific rhythm disorder. In general, a short window restricts a complete definition of the rotational/focal activation. Conversely, a long window ~ such as the entire cycle ~ can result in a failure to detect a cycle if there are small accelerations of rate in preceding beats (e.g., faster beats). The more regular ('simple') the rhythm disorder, the smaller the proportion of
the cycle length that can be required in order to establish a rotational pattern. In a complex
rhythm disorder, such as atrial fibrillation, one embodiment can typically select >50% of the
cycle length as the window duration over which to establish rotational activation. This
precise size of the first window 702 can be tailored to a specific patient, and retained in a
database for reuse, e.g., should the patient have a repeat procedure.

[00115] For example, the cycle length associated with the heart rhythm disorder is
determined to be 200 msec. Accordingly, the size of the first window is 150 msec (e.g., 200
msec * 75% = 150 msec). A different percentage may be selected. The first window 702 is
anchored at the first pair 606 of the plurality of pairs 605. A best-fit-line 704 is calculated in
reference to the pairs 607 of the plurality of pairs 605 that fall on or within the first window
702. Various algorithms can be used to determine the best-fit-line 704, based on minimizing
mean-square-error of the deviation of each pair from a linear regression, or a weighted mean-
square-error line.

[00116] The slope of the best-fit-line 704, location of the best-fit-line 704 (e.g., middle
of line) and a metric of the fit of the pairs to the best-fit-line 704 are calculated and recorded
in association with the calculated best-fit-line 704. The fit of the pairs to the best-fit-line 704
can be determined by a root-mean-squared-error (RMSE) calculation, or another algorithm
that can provide a metric of how closely the pairs fit the best-fit-line 704. The first window
702 is advanced and anchored to a successive pair as illustrated in FIG. 8.

[00117] FIG. 8 illustrates a graphical representation 800 showing the calculation of
lines that best fit pairs of the plurality of pairs 605 in a window 802 (also considered a first
window) anchored at a second pair 608. The first window 802 is of the first size, e.g., 150
msec (75% of 200 msec cycle length associated with the heart rhythm disorder).

[00118] The first window 802 is anchored at the second pair 608 of the plurality of
pairs 605. A best-fit-line 804 is calculated in reference to the pairs that fall on or within the
window 802. The slope of the best-fit-line 802, location of the best-fit-line 804 (e.g., middle
of line) and a metric of the fit of the pairs to the best-fit-line 804 are calculated and recorded
in association with the calculated best-fit-line 804. The first window 802 is advanced and
anchored to a successive pair as illustrated in FIG. 9.

[00119] FIG. 9 illustrates a graphical representation 900 showing the calculation of
lines that best fit pairs of the plurality of pairs 605 in a window 902 (also considered a first
window) anchored at a third pair 610. The window 902 is of the first size, e.g., 150 msec (75% of 200 msec cycle length associated with the heart rhythm disorder).

[00120] The first window 902 is anchored at the third pair 610 of the plurality of pairs 605. A best-fit-line 904 is calculated in reference to the pairs that fall on or within the first window 902. The slope of the best-fit-line 904, location of the best-fit-line 904 (e.g., middle of line) and a metric of the fit of the pairs to the best-fit-line 904 are calculated and recorded in association with the calculated best-fit-line 802. The first window 902 is advanced and anchored to a successive pair as illustrated in FIG. 9.

[00121] FIG. 10 illustrates a graphical representation 1000 showing the calculation of lines that best fit pairs of the plurality of pairs 605 in nth window 1002 (also considered a first window) anchored at an nth pair 618. The first window 1002 is of the first size, e.g., 150 msec (75% of 200 msec cycle length associated with the heart rhythm disorder).

[00122] The first window 1002 is anchored at the nth pair 618 of the plurality of pairs 605. A best-fit-line 1004 is calculated in reference to the pairs 1006 that fall on or within the first window 1002. For example, the n* window 1002 will include pairs 1006 of pairs 605 that remain to be processed for the relevant analysis time interval. The slope of the best-fit-line 1004, location of the best-fit-line 1004, (e.g., middle of line) and a metric of the fit of the pairs to the best-fit-line 1004, are calculated and recorded in association with the calculated best-fit-line 1004.

[00123] As illustrated in FIGS. 7-10, the first window of the first size is successively advanced and anchored to successive pairs of the plurality of pairs 605 between the first pair 606 and the nth pair 618 until all pairs 605 are processed in the analysis time interval, which generates a plurality of best-fit-lines 1008, as illustrated in FIG. 10.

[00124] FIG. 11 illustrates a graphical representation 1000 showing selection of a line that best fits pairs of the plurality of pairs 605 in a window 1106 (e.g., second window) anchored at a first pair 606. A size of the second window 1106 is defined to be a predetermined percentage (e.g., 110%) of a cycle length that is associated with the heart rhythm disorder. A different percentage may be selected.

[00125] In the foregoing example, the cycle length determined to be associated with the heart rhythm disorder is 200 msec. Accordingly, the size of the second window is 220
msec (e.g., 200 msec \(* 110\% = 220\) msec). The second window 1106 is anchored at the first pair 606 of the plurality of pairs 605. The best-fit-line 1110 is then selected within the second window 1106. For example, the fit (e.g., minimal error) of the pairs to the best-fit lines can be used to select the best-fit-line 1110 in the second window 1106.

[00126] As an example, a root-mean-squared-error (RMSE) can be used as a metric for the selection of the best-fit line 1110. Specificity, the RMSE enables selection of a best-fit line 1110 in connection with which minimal error (metric) 1108 of the pairs to the associated best-fit line. It should be noted that various other algorithms, and combinations of mentioned algorithm and/or other algorithms, can be used to select the best-fit-line 1110. The second window 1106 is advanced and anchored to line after the window as illustrated in FIG. 12.

[00127] FIG. 12 illustrates a graphical representation 1200 showing selection of a line that best fits pairs of the plurality of pairs 605 in a window 1206 (also considered a second window) anchored at a first best-fit line after the first window 1106.

[00128] In the foregoing example, the cycle length that is determined to be associated with the heart rhythm disorder is 200 msec. Accordingly, the size of the second window is 220 msec (e.g., 200 msec \(* 110\% = 220\) msec). The second window 1106 abest-fit line after the second window 1106 that is anchored at pair 616 of the plurality of pairs 605. Specifically, the anchor pair 614 of the selected best-fit line 1110 occurs at approximately 180 msec. Thereafter, half of the determined cycle length of 110 msec (e.g., 220 msec \(* 0.5\) is added to the time of 180 msec, which is a total of 290 msec. The half-cycle is added as a 'blanking period' such that the next analysis window does not overlap with the terminal portion of the current analysis window. The first best-fit line after the 290 msec is anchored at pair 616 occurring approximately at 400 msec because no other data pairs are available between approximately 290 msec and 400 msec. Accordingly, the second window 1206 extends from approximately 400 to approximately 620.

[00129] The best-fit-line 1210 is then selected within the second window 1206. For example, the fit (e.g., minimal error) of the pairs to the best-fit lines can be used to select the best-fit-line 1210 in the second window 1206.

[00130] As an example, a root-mean-squared-error (RMSE) can be used as a metric for the selection of the best-fit line 1210. Specificity, the RMSE enables selection of a best-fit line 1210 in connection with which minimal error (metric) 1208 of the pairs to the associated
best-fit line. As described before, various other algorithms, and combinations of mentioned algorithm and/or other algorithms, can be used to select the best-fit-line 1210.

[00131] As illustrated and described in reference to FIGS. 11 and 12, the second window of the second size is successively advanced and anchored to the first best-fit line after the second window 1106, until all best-fit lines are processed in the analysis time interval.

[00132] FIG. 13 is a flowchart of an example method 1300 of determining an area of one or more spatial elements that are related to progressive angular deviations of activation onset times. The method starts at operation 1302. At operation 1304, the method 1300 accesses location data and activation onset data in connection with a heart rhythm disorder (e.g., the monophasic action potential data from (MAP) representations of the signals, e.g., APM video 150). The MAP representation includes sensor.

[00133] At operation 1306, a radius (e.g., FIG. 2, radius 204) is determined for the selection of sensors in connection with a spatial element. At operation 1308, a spatial element associated with a sensor is selected (e.g., FIG. 2, spatial element 202). Thereafter, a set of sensors on or within the radius of the spatial element is determined at operation 1310.

[00134] At operation 1312, an analysis time interval is selected (e.g., 4000 msec). It should be noted that different analysis time intervals can be selected, e.g., longer or shorter than 4000 msec. At operation 1314, an activation onset time associated with a sensor in the determined set is selected. It is noted that this represents a first activation onset time (e.g., in the analysis time interval) associated with any sensor in the determined set of sensors within the radius from the spatial element.

[00135] At operation 1316, an angle is calculated from the selected spatial element to the sensor associated with the activation onset time. Thereafter, at operation 1318, a pair of values referred to as "pair") is generated. The generated pair includes the angle and the activation onset time. At operation 1320, a determination is made as to whether there any more sensors associated with the selected activation onset time. If so, the method 1300 iterates over operations 1314-1320 to generate additional pairs (e.g., pair = [angle, activation onset time]) for those sensors. If not, the method 1300 continues at operation 1322.
At operation 1322, a determination is made as to whether all activation onset times in the analysis time interval (e.g., 4000 msec) have been processed. If not, the method 1300 iterates over operations 1314-1322 to generate pairs associated with activation of the sensors in the set over the analysis time interval. If so, the method 1300 continues at operation 1324.

At operation 1324, the generated pairs are ordered by activation onset time. At operation 1326, a first window size is defined in connection with a cycle length associated with the heart rhythm disorder. For example, the first window size can be a selected percentage (e.g., 75%) smaller than the cycle length (e.g., 200 msec) associated with the heart rhythm disorder. Accordingly, the first window size can be defined to be 200 msec * 75% = 150 msec.

At operation 1328, an index is defined and set to the first pair (e.g., index pair) in the analysis time interval (e.g., 4000 msec). At operation 1330, a first window of the first window size is determined as starting from the activation onset time of the index pair. Thereafter, a subset of all pairs that is within the first window is determined at operation 1332. At operation 1334, a best-fit line is calculated in reference to the subset of pairs in the first window. The slope of the best-fit line, location of the best-fit line, and fit of the pairs to the best-fit line are determined.

At operation 1336, a determination is made as to whether all pairs in the analysis time interval (e.g., 4000 msec) have been processed. If not, the method 1300 continues at operation 1338 to increment the index to the next pair (index pair), and iterates over operations 1330-1336 until all pairs all pairs in the analysis time interval have been processed. If so, the method 1300 continues at operation 1340.

At operation 1340, a second window size is defined in connection with a cycle length associated with the heart rhythm disorder. For example, the second window size can be a selected percentage (e.g., 110%) higher than the cycle length (e.g., 200 msec) associated with the heart rhythm disorder. Accordingly, the second window size can be defined to be 200 msec * 110% = 220 msec.

At operation 1342, an index is defined and set to the first best-fit line (e.g., index line) in the analysis time interval (e.g., 4000 msec). At operation 1344, a second window of the second window size is determined starting from the index line (e.g., a pair
associated with the index line). The pair that is associated with index line can represent the beginning pair of the index line, another other pair, or some point along the index line. Thereafter, a best-fit line out of a plurality of best-fit lines is selected within the second window at operation 1346.

[00142] At operation 1348, a determination is made as to whether all best-fit lines in the analysis time interval (e.g., 4000 msec) have been processed. If not, the method 1300 continues at operation 1350 to increment the index to the next index line, and iterates over operations 1344-1348 until all best-fit lines in the analysis time interval have been processed. If so, the method 1300 continues at operation 1352.

[00143] At operation 1352, a determination is made as to whether all spatial elements have been processed. If not, the method 1300 iterates over operations 1308-1352 until progressive angular deviations of activation onset times in relation to all spatial elements have been considered. At operation 1354, at least one area having one of more of the spatial elements is determined based on one or more characteristics of the selected best-fit lines, such as that the area can be ablated to ameliorate the heart rhythm disorder. The method end at operation 1356.

[00144] FIG. 14 illustrates a general computer system that can be used to perform any one or more methods and/or computer based functions described herein. The description of FIG. 14 is provided hereinbelow after the description of FIG. 32.

[00145] FIG. 15 illustrates an example precession of a rotating source (locus) of a complex heart rhythm disorder. It should be noted that precession of the rotating source will prevent detection of rotation at fixed electrodes using classical methods.

[00146] FIG. 16 indicates disorganization that does not disturb the source. In section (1), there is shown fibrillatory conduction, i.e., disorganization away from the center of the source. In section (2), there is shown outside disorganization, i.e., peripheral disorganized activation towards the center of the source that does not perturb the central elements of the source.

[00147] FIG. 17 illustrates the concept of interruption of peripheral portions of a source, for instance, interruption of the rotating spiral arms around a rotor source, by disordered activation. This will prevent detection of sequential rotational activation at fixed
electrodes using classical methods of activation mapping, isopotential mapping, or isochronal analysis.

[00148] FIG. 18 indicates disorganization that perturbs the rate/regularity of a source. As illustrated in FIG. 18, the disorganization constrains irregularity, making it more regular. The opposite of this may also occur.

[00149] FIG. 19 indicates disorganization that perturbs the spatial localization of a source. In section (1), disorganization constrains spatial precession, making the source locus smaller and the rhythm more regular. In section (2), disorganization exacerbates source precession, the rotor precesses to another region of the heart, where it may self-terminate or be easier to treat.

[00150] FIG. 20 indicates disorganization that perturbs the source to the point of terminating the source of the disorder.

[00151] FIG. 21 illustrates mathematical approaches to identify sources through perturbations, and thus to quantify perturbations. In section (1), there is illustrated an unperturbed source, indicated by linear progressive angular deviation (PAD) correlations of X1...Xn for repeated cycles of activation. In section (2), there is illustrated source precession, with deviations of PADs from the ideal PAD correlations. In section (3), there is illustrated a discontinuous source, where external disorganized activity fuses with peripheral portions of the source. In section (4), an interrupted source is illustrated, where external disorganized activity eliminates portions of rotation around the source.

[00152] FIG. 22 is a flowchart of an example method 2200 of characterizing progressive angular deviations (PADs) of a rotational source in relation to a potential site.

[00153] At operation 2202, a potential site related to surrounding sites is selected. At operation 2204, activation onset times of the surrounding sites are ordered. At operation 2206, a determination is made as to whether there is progressive angular deviation in connection with the surrounding sites over an analysis time interval. If so, operations 2210-2214 are performed in connection with the selected potential site. In alternate embodiments, operation 2206 can be substituted with other analyses of focal beats. For example, operation 2206 can use, instead of PAD, progressive vectors, progressive rotational number,
progressive correlation, trigonometric function, or another mathematical tool. Operations 2202-2208 are iterated for each of the potential sites.

[00154] If there is progressive angular deviation in connection with a potential site, then at operation 2310, a determination is made as to whether other criteria are met, such as consistency in the progressive angular deviations and whether a plausible cycle length is possible in connection with consistent progressive angular deviations. If so, at operation 2212 a potential rotor can be indicated by such consistency and plausible cycle length. At operation 2214, the progressive angular deviations can be characterized by line slope, non-linearity (slow conduction), regionality, rate and periodicity.

[00155] FIG. 23 is a flowchart of an example method 2300 of characterizing progressive angular deviations (PADs) of a focal source in relation to a potential site.

[00156] At operation 2302, a potential site related to surrounding sites is selected. At operation 2304, activation onset times of the surrounding sites are ordered. At operation 2306, a determination is made as to whether there is progressive angular deviation in connection with the surrounding sites over an analysis time interval. If so, operations 2310-2314 are performed in connection with the selected potential site. In alternate embodiments, operation 2306 can be substituted with other analyses of focal beats. For example, operation 2306 can use, instead of PAD, progressive vectors (showing zero sum vector in all directions indicative of focal activation), progressive focal number, progressive correlation, trigonometric function, or another mathematical tool. Operations 2302-2308 are iterated for each of the potential sites.

[00157] If there is progressive angular deviation in connection with a potential site, then at operation 2310, a determination is made as to whether other criteria are met, such as consistency in the progressive angular deviations and whether a plausible cycle length is possible in connection with consistent progressive angular deviations. If so, at operation 2312 a potential focal source can be indicated by such consistency and plausible cycle length. At operation 2314, the progressive angular deviations can be characterized by line slope, non-linearity (slow conduction), regionality, rate and periodicity.

[00158] FIG. 24 is a pictorial representation of successive rotations of a rotor during atrial fibrillation in a patient, each of which is consistent from cycle to cycle and is detected by consistent and uninterrupted angular deviations (e.g., angles theta from 0 to 2 pi) from
cycle to cycle. It should be noted that this rotation is at the center of a stable source for atrial fibrillation, but could also lie within ventricular fibrillation, or a simple rhythm such as atrial flutter.

[00159] FIG. 25 is a pictorial representation of successive rotations of a rotor within a complex rhythm (e.g., atrial fibrillation) in a patient. The rotor is stable but interrupted by activation from outside the rotor, which may indicate fibrillatory conduction or another source. The rotor also precesses ('wobbles') showing slight spatial movement but within a stable spatial area. The progressive angular deviation plots show straight lines of theta against time, but with some biological noise reflecting these interruptions.

[00160] FIG. 26 is a pictorial representation of successive rotations of 2 concurrent rotors in a patient with atrial fibrillation. As illustrated, both rotors are stable with some interruptions by the fibrillatory milieu. Rotor 1 is interrupted more than rotor 2. Both rotors also show slight precession ('wobble'). Accordingly, progressive angular deviation plots show straight lines of theta against time, but with some biological noise reflecting these interruptions.

[00161] FIG. 27 is a flowchart for analyzing a polar analysis of rotations (PAR) for a rotational activation trail using polar analyses. Each operation provides a polar index of rotation, which are combined (or weighted) to determine a rotor. Operation 1 determines activation delay for all adjacent sites for an entire tracing (at least a majority of one complete cycle). In general, conduction time within human atria is 40-200 cm/second, such that activation time delay between electrodes spaced 0.6 cm apart is 3-15 milliseconds (typically 5-10 msec), scaled appropriately for different spacing between electrodes. Conversely, if a rotor is present then activation at adjacent electrodes could be separated by an entire cycle length if they lie at the head versus tail, i.e., activation has to complete a rotation to reach the tail (up to ~200 msec). Operation 2 determines the angular displacement for successively activated sites within the atria. If successively activated sites mostly show the angular deviation expected from a rotation, i.e., 2π/8 (for 8 surrounding electrodes), then the central electrode is consistent with the core of rotor. Operation 3 examines and determines systematically for all sites in the chamber, if successive surrounding electrodes (in a clock face type of orientation) trace successive angular deviations over time. If so, this is consistent with rotational activation. Operation 4 determines the number of activations at each surrounding electrode per cycle. If this is less than one (1), then dropout (or block into
that site) may exist. If this is more than one (1), then double counting or disorganization (fibrillatory conduction) may exist.

[00162] FIG. 28 is a flowchart of an example method of analyzing a polar analysis of rotations (PAR) for a focal (centrifugal) activation trail. Each operation provides a focal index of rotation, combined (or weighted) equally or non-uniformly to determine a focal source. Operation 1 determines activation delay for all adjacent sites for an entire tracing (at least one complete cycle). In general, conduction time within human atria is 40-200 cm/second, such that activation time delay between electrodes spaced 0.6 cm apart is 3-15 msec (typically 5-10 msec), scaled appropriately for different spacing between electrodes. For a focal source, there will be simultaneous activation of electrodes on concentric circles, unless/until the source disorganizes (fibrillatory conduction). Operation 2 determines angular displacement for successively activated sites within the atria. If successively activated sites mostly show patterns expected from a focal source, then the central electrode is consistent with a focal origin. Operation 3 examines and determines systematically for all sites in the chamber, if successively activated electrodes (in a clock face type of orientation) trace zero angular deviations along each radius from the origin, i.e., centrifugal. Operation 4 determines the number of activations at each surrounding electrode per cycle. If this is less than one (1), then dropout may exist (or block into that site). If this is more than one (1), then double counting or disorganization (fibrillatory conduction) may exist.

[00163] FIG. 29 illustrates a counterclockwise rotor in the left atrium during atrial fibrillation in a patient.

[00164] FIG. 30 illustrates detection of the rotor core by polar analysis of rotations (PAR). The inset (right) shows a clear polar spiral line indicating an uninterrupted rotor at the central point (labeled H5 in the spatial plot in FIG. 29). The top graph indicates cumulative angular deviation in number of rotational spins around this central site (vertical axis, 20) for 160 activations at 8 surrounding electrodes (i.e., 20 spins). The top left angular displacement histogram indicates that each angular position around the central core (i.e., all surrounding 8 electrodes) are activated 20 times each (vertical scale), i.e., equally per each location. The electrode with 19 activations indicates possible signal drop out. The middle left time delay histogram shows that many adjacent sites in the entire field activate with delays of 25 msec, 35 msec or 45 msec, far longer than supported by passive conduction. The bottom left angular position histogram shows that all sites (i.e., 160 activations, for 20 activations at 8
sites activated successively in time) are separated by an angular deviation of 2π/8, i.e., π/4 radians - the angular deviation between two (2) adjacent electrodes.

[00165] FIG. 31 illustrates polar analyses of rotation (PAR) for a site just outside the rotor (GH56). Is should be noted that the raw polar plot shows additional lines that deviate from a spiral, indicating subsidiary (fibrillatory) activation. The top central graph shows complete rotations (vertical scale) over 240 activations at 12 surrounding electrodes (i.e., 20 spins). The top left angular displacement histogram shows that most electrodes (vertical scale) are activated per cycle. The middle left time delay histogram shows the beginning of a bimodal distribution - in that a dominant number of electrodes activate rapidly (i.e., within 5-10 msec), indicating possible passive activation, with some still activating late as expected of rotational activity. The bottom left angular position histogram shows that many sites (vertical scale) activated successively in time are often separated by π/4, but often by π/2 radians (i.e., further away - not rotational).

[00166] FIG. 32 illustrates polar analysis of rotation (PAR) for a site distant from the rotor (EF23). That raw polar plot shows nearly chaotic activity that does not trace a spiral, which indicates non-rotational activation. The top central graph shows that the cumulative rotational counter does not rise progressively, and actually reverses periodically (falls below zero, i.e., anti-phase). The top left angular displacement histogram shows that many electrodes (vertical scale) are not activated at all, likely indicating signal dropout or regions of block. This metric thus enables one to identify sites - where the organized rotor domain ends and fibrillatory conduction starts. The middle left time delay histogram shows that nearly all electrodes activate rapidly (i.e., within 5-15 msec) indicating passive conduction and inconsistent head-meets-tail rotation. The bottom left angular position histogram shows that sites activated successively in time (vertical scale) are often widely separated in space (i.e., π/4, π/2 and even π radians - i.e., up to 180 degrees separated). This indicates very little or no sequential organization - not rotational.

[00167] In accordance with an embodiment, an aggregate, summated, or average representation is provided to combine the identified regions where each source has been identified over time. This preferred embodiment of the representation is dynamically updated as more data is processed to identify regions where a source is present. Such a representation may include an image, a series of images, or a composite movie of the images in continuous or 'time-lapse' form. Each image conveys the three-dimensional structure of the mapped...
biological (heart) chamber together with source identification. Source identification may take the form of relative numerical percentages, ratios, color coding, three dimensional 'bar charts' or 'topological' maps, or other relative information to provide a user with qualitative and/or quantitative information regarding how frequently a source is identified in a particular region of the representation of the heart.

[00168] These aggregate, summed or average quantities may be simple summations, or may be weighted based on criteria such as the number of rotations of the source, the size of the chamber influenced ('controlled') by the source, wavefront propagation from/to the source, stability of wavefronts associated with the source, centrifugal patterns such as those that may be associated with focal sources, or other factors. Information may also be provided to convey how likely a region is to harbor a source. In this way, less 'strong' or less 'convincing' sources, such as those that are continuously interrupted in their course by interaction with additional sources, may be represented differently from definitive source regions. Other embodiments of the aggregate, summed, or average representation may include video images with source regions and/or characteristics associated with sources, numerical displays, icons, or other representative symbols to identify the spatial region displayed either on an isolated display, a three dimensional abstract representation, a three dimensional representation of the cardiac tissue, polar representations, or other geometric or cartographic representations that correlate to the cardiac tissue. These images are thus n-dimensional, providing three (3) structural dimensions, and at least one (1) dimension for the source parameter at each structural location.

[00169] In accordance with another embodiment, a method associated with identifying and treating a source of a heart rhythm disorder is disclosed. In accordance with the method, a spatial element associated with a region of the heart is selected. Progressive rotational activations or progressive focal activations are determined in relation to the selected spatial element over a period of time. The selecting and determining are repeated over multiple periods of time. A source parameter of rotational activations or focal activations is determined, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart. The determining of a source parameter is repeated for multiple regions of the heart. A representation of the source parameter is displayed for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder.
In accordance with a further embodiment, a system associated with identifying and treating a source of a heart rhythm disorder is disclosed. The system includes a processor and a memory storing instructions that, when executed by the processor, cause the processor to perform the following operations. The operations include selecting a spatial element associated with a region of the heart, and determining progressive rotational activations or progressive focal activations in relation to the selected spatial element over a period of time. The operations also include repeating the selecting and determining over multiple periods of time, and determining a source parameter of rotational activations or focal activations, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart. The operations further include repeating the determining of a source parameter for multiple regions of the heart. Furthermore, the operations include displaying a representation of the source parameter for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder.

In accordance with yet another embodiment, there is disclosed a storage medium storing instructions that, when executed by the processor, cause the processor to perform operations associated with identifying and treating a source of a heart rhythm disorder. The operations include selecting a spatial element associated with a region of the heart, and determining progressive rotational activations or progressive focal activations in relation to the selected spatial element over a period of time. The operations also include repeating the selecting and determining over multiple periods of time, and determining a source parameter of rotation activations or focal activations, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart. The operations further include repeating the determining of a source parameter for multiple regions of the heart. Furthermore, the operations include displaying a representation of the source parameter for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder.

In some embodiments or aspects, the source parameter can be associated with a frequency of successive rotational activations in the region of the heart. The source parameter can be associated with a frequency of progressive angular displacement in the region of the heart. Moreover, the source parameter can be a regularity with which the rotational activations or focal activations are present. In this regard, the regularity may be
one of periodicity, repetitiveness, and/or frequency of occurrence of rotational or focal activations.

[00173] In some embodiments or aspects, the representation can use an arithmetic mean of the source parameter of the region over time. The representation can also use a geometric or other mean of the source parameter of the region over time. Moreover, the representation can use a weighted average of the source parameter of the region over time.

[00174] In accordance with still another embodiment, a method of identifying and treating a source of a heart rhythm disorder is disclosed. In accordance with the method, a spatial element associated with a region of the heart is selected. Progressive rotational activations or progressive focal activations are determined in relation to the selected spatial element over a period of time. The selecting and determining are repeated over multiple periods of time. A source parameter of rotational activations or focal activations is determined, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart. The determining of a source parameter is repeated for multiple regions of the heart. A representation of the source parameter is displayed for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder. Thereafter, a region of the heart associated with the shape is selectively modified in order to terminate or alter the heart rhythm disorder.

[00175] FIGs. 33A-33D illustrate examples of averaging/aggregating of concurrent sources using isochronal representations of rotational activation sources at two different regions ("site 1" (3300) and "site 2" (3302)), surrounded by disorganized activation over four different time segments in the same patient. Precession of a first counterclockwise rotational activation source is noted at site 1 (3300) (with "wobble") in FIGs. 33A, 33B, and 33D. Similarly, precession of a second counterclockwise rotational source is noted at site 2 (3302) (with "wobble") in FIGs 33B and 33C. As these maps have slightly different the appearances during different time segments, it would be warranted to develop a visual representation that can combine the information from each of these time segments, potentially using a source parameter, in order to determine the shape of the region of precession of each source. This will aid in the diagnosis and potential treatment of the source of the heart rhythm disorder.
FIG. 14 is a block diagram of an illustrative embodiment of a general computer system 1400. The computer system 1400 can be the signal processing device 114 and the computing device 116 of FIG. 1. The computer system 1400 can include a set of instructions that can be executed to cause the computer system 1400 to perform any one or more of the methods or computer based functions disclosed herein. The computer system 1400, or any portion thereof, may operate as a standalone device or may be connected, e.g., using a network or other connection, to other computer systems or peripheral devices. For example, the computer system 1400 may be operatively connected to signal processing device 114 and analysis database 118.

In operation as described in FIGS. 1-33, the identification of source(s) of heart rhythm disorders as described herein can be used to identify patients in whom therapy can be effective and to assist in guiding such therapy, which can include delivery of one or more of ablation, electrical energy, mechanical energy, drugs, cells, genes and biological agents to at least a portion of the identified source(s) of the heart.

The computer system 1400 may also be implemented as or incorporated into various devices, such as a personal computer (PC), a tablet PC, a personal digital assistant (PDA), a mobile device, a palmtop computer, a laptop computer, a desktop computer, a communications device, a control system, a web appliance, or any other machine capable of executing a set of instructions (sequentially or otherwise) that specify actions to be taken by that machine. Further, while a single computer system 1400 is illustrated, the term "system" shall also be taken to include any collection of systems or sub-systems that individually or jointly execute a set, or multiple sets, of instructions to perform one or more computer functions.

As illustrated in FIG. 14, the computer system 1400 may include a processor 1402, e.g., a central processing unit (CPU), a graphics-processing unit (GPU), or both. Moreover, the computer system 1400 may include a main memory 1404 and a static memory 1406 that can communicate with each other via a bus 1426. As shown, the computer system 1400 may further include a video display unit 1410, such as a liquid crystal display (LCD), an organic light emitting diode (OLED), a flat panel display, a solid-state display, or a cathode ray tube (CRT). Additionally, the computer system 1400 may include an input device 1412, such as a keyboard, and a cursor control device 1414, such as a mouse. The computer system
1400 can also include a disk drive unit 1416, a signal generation device 1422, such as a speaker or remote control, and a network interface device 1408.

[00180] In a particular embodiment, as depicted in FIG. 14, the disk drive unit 1416 may include a computer-readable medium 1418 in which one or more sets of instructions 1420, e.g., software, can be embedded. Further, the instructions 1420 may embody one or more of the methods or logic as described herein. In a particular embodiment, the instructions 1420 may reside completely, or at least partially, within the main memory 1404, the static memory 1406, and/or within the processor 1402 during execution by the computer system 1400. The main memory 1404 and the processor 1402 also may include computer-readable media.

[00181] In an alternative embodiment, dedicated hardware implementations, such as application specific integrated circuits, programmable logic arrays and other hardware devices, can be constructed to implement one or more of the methods described herein. Applications that may include the apparatus and systems of various embodiments can broadly include a variety of electronic and computer systems. One or more embodiments described herein may implement functions using two or more specific interconnected hardware modules or devices with related control and data signals that can be communicated between and through the modules, or as portions of an application-specific integrated circuit. Accordingly, the present system encompasses software, firmware, and hardware implementations.

[00182] In accordance with various embodiments, the methods described herein may be implemented by software programs tangibly embodied in a processor-readable medium and may be executed by a processor. Further, in an exemplary, non-limited embodiment, implementations can include distributed processing, component/object distributed processing, and parallel processing. Alternatively, virtual computer system processing can be constructed to implement one or more of the methods or functionality as described herein.

[00183] It is also contemplated that a computer-readable medium includes instructions 820 or receives and executes instructions 1420 responsive to a propagated signal, so that a device connected to a network 1424 can communicate voice, video or data over the network 1424. Further, the instructions 1420 may be transmitted or received over the network 1424 via the network interface device 1408.
While the computer-readable medium is shown to be a single medium, the term "computer-readable medium" includes a single medium or multiple media, such as a centralized or distributed database, and/or associated caches and servers that store one or more sets of instructions. The term "computer-readable medium" shall also include any medium that is capable of storing, encoding or carrying a set of instructions for execution by a processor or that cause a computer system to perform any one or more of the methods or operations disclosed herein.

In a particular non-limiting, example embodiment, the computer-readable medium can include a solid-state memory, such as a memory card or other package, which houses one or more non-volatile read-only memories. Further, the computer-readable medium can be a random-access memory or other volatile re-writable memory. Additionally, the computer-readable medium can include a magneto-optical or optical medium, such as a disk or tapes or other storage device to capture carrier wave signals, such as a signal communicated over a transmission medium. A digital file attachment to an e-mail or other self-contained information archive or set of archives may be considered a distribution medium that is equivalent to a tangible storage medium. Accordingly, any one or more of a computer-readable medium or a distribution medium and other equivalents and successor media, in which data or instructions may be stored, are included herein.

In accordance with various embodiments, the methods described herein may be implemented as one or more software programs running on a computer processor. Dedicated hardware implementations including, but not limited to, application specific integrated circuits, programmable logic arrays, and other hardware devices can likewise be constructed to implement the methods described herein. Furthermore, alternative software implementations including, but not limited to, distributed processing or component/object distributed processing, parallel processing, or virtual machine processing can also be constructed to implement the methods described herein.

It should also be noted that software that implements the disclosed methods may optionally be stored on a tangible storage medium, such as: a magnetic medium, such as a disk or tape; a magneto-optical or optical medium, such as a disk; or a solid-state medium, such as a memory card or other package that houses one or more read-only (non-volatile) memories, random access memories, or other re-writable (volatile) memories. The software may also utilize a signal containing computer instructions. A digital file attachment to e-mail
or other self-contained information archive or set of archives is considered a distribution medium equivalent to a tangible storage medium. Accordingly, a tangible storage medium or distribution medium as listed herein, and other equivalents and successor media, in which the software implementations herein may be stored, are included herein.

[00188] Thus, a system and method of identifying a source of a heart rhythm disorder, by identification of rotational of focal activation in relation to one or more spatial elements associated with the source of the heart rhythm disorder, have been described. Although specific example embodiments have been described, it will be evident that various modifications and changes may be made to these embodiments without departing from the broader scope of the invention. Accordingly, the specification and drawings are to be regarded in an illustrative rather than a restrictive sense. The accompanying drawings that form a part hereof, show by way of illustration, and not of limitation, specific embodiments in which the subject matter may be practiced. The embodiments illustrated are described in sufficient detail to enable those skilled in the art to practice the teachings disclosed herein. Other embodiments may be utilized and derived therefrom, such that structural and logical substitutions and changes may be made without departing from the scope of this disclosure. This Detailed Description, therefore, is not to be taken in a limiting sense, and the scope of various embodiments is defined only by the appended claims, along with the full range of equivalents to which such claims are entitled.

[00189] Such embodiments of the inventive subject matter may be referred to herein, individually and/or collectively, by the term "invention" merely for convenience and without intending to voluntarily limit the scope of this application to any single invention or inventive concept if more than one is in fact disclosed. Thus, although specific embodiments have been illustrated and described herein, it should be appreciated that any arrangement calculated to achieve the same purpose may be substituted for the specific embodiments shown. This disclosure is intended to cover any and all adaptations or variations of various embodiments. Combinations of any of the above-described embodiments, and other embodiments not specifically described herein, may be used and are fully contemplated herein.

[00190] The Abstract is provided to comply with 37 C.F.R. §1.72(b) and will allow the reader to quickly ascertain the nature and gist of the technical disclosure. It is submitted with
the understanding that it will not be used to interpret or limit the scope or meaning of the
claims.

[00191] In the foregoing description of the embodiments, various features are grouped
together in a single embodiment for the purpose of streamlining the disclosure. This method
of disclosure is not to be interpreted as reflecting that the claimed embodiments have more
features than are expressly recited in each claim. Rather, as the following claims reflect,
inventive subject matter lies in less than all features of a single disclosed embodiment. Thus,
the following claims are hereby incorporated into the Description of the Embodiments, with
each claim standing on its own as a separate example embodiment.
What is claimed is:

1. A method associated with identifying and treating a source of a heart rhythm disorder, the method comprising:
   - selecting a spatial element associated with a region of the heart;
   - determining progressive rotational activations or progressive focal activations in relation to the selected spatial element over a period of time;
   - repeating the selecting and determining over multiple periods of time;
   - determining a source parameter of rotational activations or focal activations, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart;
   - repeating the determining of a source parameter for multiple regions of the heart; and
   - displaying a representation of the source parameter for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder.

2. The method of claim 1, wherein the source parameter is associated with a frequency of successive rotational activations in the region of the heart.

3. The method of claim 1, wherein the source parameter is associated with a frequency of progressive angular displacement in the region of the heart.

4. The method of claim 1, wherein the source parameter is a regularity with which the rotational activations or focal activations are present.

5. The method of claim 4, wherein the regularity is one of periodicity, repetitiveness, and/or frequency of occurrence of rotational or focal activations.

6. The method of claim 1, wherein the representation uses an arithmetic mean of the source parameter of the region over time.

7. The method of claim 1, wherein the representation uses a geometric or other mean of the source parameter of the region over time.
8. The method of claim 1, wherein the representation uses a weighted average of the source parameter of the region over time.

9. The method of claim 1, further comprising displaying the representation of the source parameter on at least one of an isolated display, a three-dimensional abstract representation, a three-dimensional representation of the cardiac tissue or a polar representation.

10. A system associated with identifying and treating a source of a heart rhythm disorder, the system comprising:
    a processor; and
    a memory storing instructions that, when executed by the processor, cause the processor to perform operations comprising:
    selecting a spatial element associated with a region of the heart;
    determining progressive rotational activations or progressive focal activations in relation to the selected spatial element over a period of time;
    repeating the selecting and determining over multiple periods of time;
    determining a source parameter of rotational activations or focal activations, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart;
    repeating the determining of a source parameter for multiple regions of the heart; and
    displaying a representation of the source parameter for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder.

11. The system of claim 10, wherein the source parameter is associated with a frequency of successive rotational activations in the region of the heart.

12. The system of claim 10, wherein the source parameter is associated with a frequency of progressive angular displacement in the region of the heart.

13. The system of claim 10, wherein the source parameter is a regularity with which the rotational activations or focal activations are present.
14. The system of claim 13, wherein the regularity is one of periodicity, repetitiveness, and/or frequency of occurrence of rotational or focal activations.

15. The system of claim 10, wherein the representation uses an arithmetic mean of the source parameter of the region over time.

16. The system of claim 10, wherein the representation uses a geometric or other mean of the source parameter of the region over time.

17. The system of claim 10, wherein the representation uses a weighted average of the source parameter of the region over time.

18. The system of claim 10, wherein the representation of the source parameter is displayed on at least one of an isolated display, a three-dimensional abstract representation, a three-dimensional representation of the cardiac tissue or a polar representation.

19. A storage medium storing instructions that, when executed by the processor, cause the processor to perform operations associated with identifying and treating a source of a heart rhythm disorder, the operations comprising:
   selecting a spatial element associated with a region of the heart;
   determining progressive rotational activations or progressive focal activations in relation to the selected spatial element over a period of time;
   repeating the selecting and determining over multiple periods of time;
   determining a source parameter of rotational activations or focal activations, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart;
   repeating the determining of a source parameter for multiple regions of the heart; and
   displaying a representation of the source parameter for each of the multiple regions of the heart to identify a shape representing the source of the heart rhythm disorder.

20. The storage medium of claim 19, wherein the source parameter is associated with a frequency of successive rotational activations in the region of the heart.
21. The storage medium of claim 19, wherein the source parameter is associated with a frequency of progressive angular displacement in the region of the heart.

22. The storage medium of claim 19, wherein the source parameter is a regularity with which the rotational activations or focal activations are present.

23. The storage medium of claim 22, wherein the regularity is one of periodicity, repetitiveness, and/or frequency of occurrence of rotational or focal activations.

24. The storage medium of claim 19, wherein the representation uses an arithmetic mean of the source parameter of the region over time.

25. The storage medium of claim 19, wherein the representation uses a geometric or other mean of the source parameter of the region over time.

26. The storage medium of claim 19, wherein the representation uses a weighted average of the source parameter of the region over time.

27. The storage medium of claim 19, wherein the representation of the source parameter is displayed on at least one of an isolated display, a three-dimensional abstract representation, a three-dimensional representation of the cardiac tissue or a polar representation.

28. A method of identifying and treating a source of a heart rhythm disorder, the method comprising:
   selecting a spatial element associated with a region of the heart;
   determining progressive rotational activations or progressive focal activations in relation to the selected spatial element over a period of time;
   repeating the selecting and determining over multiple periods of time;
   determining a source parameter of rotational activations or focal activations, wherein the source parameter indicates consistency of successive rotational activations or focal activations in relation to a portion of the region of the heart;
   repeating the determining of a source parameter for multiple regions of the heart;
displaying a representation of the source parameter for each of the multiple regions of
the heart to identify a shape representing the source of the heart rhythm disorder; and
selectively modifying a region of the heart associated with the shape in order to
terminate or alter the heart rhythm disorder.
FIG. 2

X = 0
Y = 1

ANGLE = ATAN(1/0)
ANGLE = pi/2 = 90°
t = 10 ms
PAIR1 = (pi/2, 10)

FIG. 3

X = 0
Y = 2

ANGLE = ATAN(2/0)
ANGLE = pi/2 = 90°
t = 36 ms
PAIR2 = (pi/2, 36)
1302 START
1304 ACCESS SENSOR LOCATION DATA AND ACTIVATION ONSET DATA (MAP) ASSOCIATED WITH A CARDIAC RHYTHM DISORDER
1306 DETERMINE A RADIUS TO SELECT SENSORS FOR ANALYSIS
1308 SELECT A SPATIAL ELEMENT ASSOCIATED WITH A SENSOR
1310 DETERMINE A SET OF SENSORS ON OR WITHIN THE RADIUS OF THE SPATIAL ELEMENT
1312 SELECT AN ANALYSIS TIME INTERVAL (E.G., 4000 MSEC)
1314 SELECT AN ACTIVATION ONSET TIME ASSOCIATED WITH A SENSOR IN DETERMINED SET
1316 CALCULATE ANGLE FROM THE SELECTED SPATIAL ELEMENT TO THE ASSOCIATED SENSOR
1318 GENERATE A PAIR THAT INCLUDES THE ANGLE AND THE ACTIVATION ONSET TIME
1320 MORE SENSORS ASSOCIATED WITH THE SELECTED ACTIVATION ONSET TIME? YES
1322 ALL ACTIVATION ONSET TIMES IN THE ANALYSIS TIME INTERVAL PROCESSED? NO
1324 ORDER PAIRS BY ACTIVATION ONSET TIME
1326 DEFINE A FIRST WINDOW SIZE (E.G., 75% OF MEDIAN CL ASSOCIATED WITH DISORDER)
1328 SET INDEX TO THE FIRST PAIR (INDEX PAIR) IN THE ANALYSIS TIME INTERVAL

FIG. 13
DETERMINE A FIRST WINDOW STARTING AT THE ACTIVATION ONSET TIME OF THE INDEX PAIR

DETERMINE A SUBSET OF PAIRS WITHIN THE FIRST WINDOW

CALCULATE A BEST FIT LINE IN REFERENCE TO THE PAIRS IN THE FIRST WINDOW (E.G., SLOPE OF LINE LOCATION OF LINE, AND FIT OF PAIRS TO LINE)

ALL PAIRS IN THE ANALYSIS TIME INTERVAL PROCESSED?

YES

DEFINE A SECOND WINDOW SIZE (E.G., 110% OF MEDIAN CL ASSOCIATED WITH DISORDER)

SET INDEX TO THE FIRST BEST FIT LINE (INDEX LINE) IN THE ANALYSIS TIME INTERVAL

DETERMINE A SECOND WINDOW STARTING AT THE INDEX LINE (E.G., MIDDLE OF LINE)

SELECT A BEST FIT LINE IN THE SECOND WINDOW (E.G., SLOPE AND LOCATION OF LINE)

ALL BEST FIT LINES IN THE ANALYSIS TIME INTERVAL PROCESSED?

NO

YES

ALL SPATIAL ELEMENTS PROCESSED?

YES

DETERMINE AT LEAST ONE ARE INCLUDING ONE OR MORE OF THE SPATIAL ELEMENTS BASED ON ONE OR MORE CHARACTERISTICS OF THE BEST FIT LINES FOR ABLATION

END

FIG. 13
CONTINUED
FIG. 17

FIG. 18
FOR EACH POTENTIAL SITE OF ROTATION

ORDER ACTIVATION TIME ONSETS OF SURROUNDING SITES

PROGRESSIVE ANGULAR DISPLACEMENT (LINE) IN TIME?

YES

OTHER CRITERIA MET (CONSISTENT, PLAUSIBLE CL)?

NO

NEXT POTENTIAL SITE OF ROTATION

POTENTIAL ROTOR

CHARACTERIZE LINE SLOPE, NON-LINEARITY (SLOW CONDUCTION) REGIONALITY, RATE, PERIODICITY

FIG. 22
High Level Pseudocode: Focal Source

For each potential focal source

Order activation time onsets of surrounding sites

Centrifugal Angular Patterns In Time?

Yes

Other Criteria Met (consistent, plausible CL)?

No

Next potential focal source

Potential Focal source

Characterize line slope, non-linearity (slow conduction), regionality, rate, periodicity

FIG. 23
Polar Analysis for Rotors: Pseudocode

Entire field: Do adjacent sites show delayed activity (i.e. head-meets-tail)

Entire field: Do successively activated sites trace a rotational arc?

For each potential site of rotation

Determine if activation at successive angular positions trace continuous rotation

Determine if surrounding electrodes activate once per cycle

Other Criteria Met (consistent, plausible CL)?

Potential Rotor

FIG. 27
Polar Analysis for Focal Sources: Pseudocode

Entire field: Do many sites show near-simultaneous activity?

Entire field: Do near-simultaneous sites lie across angles? (i.e. not planar)

For each potential focal source activation trail

Is activation at successive angular positions near simultaneous (circle)?

Determine if surrounding electrodes activate once per cycle

Other Criteria Met (consistent, plausible CL)?

Potential Focal Source
